VARIABILITY IN RESPONSE TO DRUGS

CHAIRMAN'S ADDRESS

ERWIN E. NELSON, M.D.

NEW ORLEANS

It is my intent in this paper briefly to call attention to a type of observation which has come to be commonplace to the pharmacologist but which is perhaps not brought so forcefully to the attention of those whose interest is therapeutics rather than pharmacology. This is the matter of the variability in response to drugs. I do not mean to infer that the physician does not recognize that patients do vary in this respect. Indeed, one of the factors in the successful treatment of disease is the physician's ability to recognize and to correct for such deviations from expected behavior. It is to be emphasized, however, that variability—individual variation—is not a perverse disturbance but is rather the condition to be anticipated. It represents, in fact, the normal—the expected situation—if the observations of the pharmacologist in the laboratory have any validity.

The direction that pharmacology has taken in recent years has forced the pharmacologist to a recognition and consideration of this matter. Much of the earlier work was essentially descriptive—morphologic, if the analogy may be permitted. Interest was chiefly in the qualitative properties of drugs rather than in their quantitative differences. But in the search for new therapeutic agents, in the collaboration between the organic chemist and the pharmacologist, it became necessary to develop methods of comparison as well as of contrast. Moreover, there came about a growing appreciation of the necessity of an accurate standardization of drugs. These and other factors have contributed to the development of quantitative methods in pharmacology.

In the comparison of a series of new synthetic products it is important to know the relative toxicity of the different members, since obviously toxicity may be the limiting factor in the use of a drug. The measure of toxicity that is most easily determined, the one that has the clearest end point, is the ability to kill. There is thus found in the literature, even up to the present day, a determination for drugs which is called the M. L. D. (minimum lethal dose). This figure is obtained by injecting a series of increasing doses into a series of animals until a dose is found that kills. Usually the groups have been small and there has been

little or no effort at determining how many animals would survive this dose. The minimum lethal doses so determined probably did have some value because they did serve as a means of relating roughly therapeutic activity to toxicity. Today, however, it has become clear to the pharmacologist that this expression in the sense originally used is not exact either for animals or for man. In the light of present day information the acceptable expression is the L. D. 50, the dose that can be expected to kill 50 per cent of a considerable group of animals. The derivation of this expression will be discussed later.

There are in use today two simple methods of determining the toxicity of a substance when its ability to kill is used as the end point. One of these is that used in the well known assay of digitalis in terms of "cat units." A well diluted solution of the active material is slowly injected intravenously into cats until death by digitalis poisoning of the heart occurs. The dose required to kill each individual cat is then expressed in terms of amount per unit weight. Most cardiologists seem to believe that this figure is, or should be, about 0.1 Gm. of digitalis per kilogram of cat. Actually any individual animal may be killed by an amount which is much smaller than this, or it may require a considerably greater amount. In the case of cats, for example, de Lind van Wijngaarden¹ in the laboratory of Magnus has shown that some cats require more than two and one half times the dose required for others. Here obviously the expression minimum lethal dose has no meaning except for the cat on which the determination was made. However, if a large number of such lethal doses are determined, while they differ over a wide range, the mean lethal dose (the average for the group) is the one that occurs most frequently, and the ones that differ most from the mean occur least often, the distribution being relatively symmetrical. The frequency polygon drawn from this distribution is of course also correspondingly symmetrical (chart 1).

There is another graphic expression of such results; that is, by integrating the values given in the frequency polygon. In this method the mortality in the group is plotted on the ordinate, and dosage required to kill on the abscissa. Since any animal that died from a small dose would certainly have been killed by larger doses, any point on the plotted curve is made to include the mortality not only for that dose but for all animals in the groups killed by smaller doses. The resultant curve is the well known sigmoid or S shaped curve (chart 2) familiar to all pharmacologists. It is merely the graphic expression of the variability in response. However, its significance can be seen if one recognizes that any particular point on the curve can be considered to represent

From the Department of Pharmacology, Tulane University of Louisiana School of Medicine.

Read before the Section on Pharmacology and Therapeutics at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

1. Lind van Wijngaarden, C. de: Untersuchungen über die Wirkungsstärke von Digitalispräparate, Arch. f. exper. Path. u. Pharmacol. 113: 40, 1926.

the expected mortality if all the members of a series were injected with the dosage corresponding to that particular point on the abscissa. Experimentally it has been found that the predicted results are most nearly obtained for the middle part of the curve. Today the accepted expression for toxicity is the L. D. 50; that is, the dose that will kill 50 per cent of a group of animals

Chart 1.—Frequency polygon showing the distribution around the mean value of the lethal doses of digitalis for different cats. Numbers of cats are shown on the ordinates; on the abscissa 0 represents the mean value, with deviations from this shown as percentages plus and minus (after de Lind van Wijngaarden¹).

sufficiently large. One may interject parenthetically that when digitalis is examined in this fashion it is necessary to standardize the anesthetic, the rate of injection, possibly the dilution, and other factors. The "cat unit" in the sense often used today varies not only because of variations in potency of digitalis but also because of variations in pharmacologists. Therefore, as an expression of an absolute value it is of somewhat restricted significance except in the laboratory where it has been determined.

The second method of determining toxicity by use of the fatal dose determination is one in which the individual dose for each animal is not determined. In the application of this method, groups of animals as comparable as possible as to weight, sex, state of nutrition and other factors are used. For obvious reasons small animals, frogs, mice, rats, insects and goldfish, are commonly employed. Into all the members of several such groups are injected doses of increasing amounts, each member of a particular group however getting the dose previously decided on for that group. If the old conception of the minimum lethal dose were correct, all of the groups below a certain dose level would survive, all above that point would be killed. This is not the case, as has been shown many times with many different substances. For example, in a study of the toxicity of strychnine salicylate for male rats from 6 to 8 months old it was found that 1.5 mg. per kilogram killed less than 10 per cent of a group, 2 mg. per kilogram about 30 per cent and 3 mg. per kilogram more than 90 per cent.² Obviously there is a variation in susceptibility, and when the data are plotted in the same fashion as indicated for digitalis with the percentage killed on the ordinate against the dosage on the abscissa, the same type of S shaped curve is obtained. In the particular study from which these data are taken, quite different values were reported for animals of the opposite sex and for different ages. Females were found more susceptible than males, and the toxicity decreased with age.

2. Poe, C. F.; Suchy, J. F., and Witt, N. F.: Toxicity of Strychnine for Male and Female Rats of Different Ages, *J. Pharmacol. & Exper. Therap.* 58: 239 (Nov.) 1936.

These curves, which after all are only the graphic expression of the variability of response of animals to these particular toxic substances, are not unique. Similar curves can be plotted for the actions of a variety of drugs in which the end point is definite enough to be clearly recognized. There may be less symmetry than is here shown; the curves may rise more rapidly or be more flattened, but in a general way it may be said that the variability that underlies the records is a biologic phenomenon; it is the behavior that one has come to expect.

What is the concern of the physician with such experiments—with curves that are derived often from toxic actions? Often, it is true, he is unaware of such variability because of the difficulty in recognizing degrees of effect, of establishing comparable levels of action. In other cases, in the induction of anesthesia for example, variability is recognized but correction is at once made for it. The anesthetist modifies the concentration or the respiratory activity until the desired end point is reached.

A number of years ago Hanzlik³ gave salicylates to a large group of patients to the point of induction of symptoms of intolerance. When his data are arranged in the fashion indicated for the toxicity of digitalis for cats, the sigmoid curve results. Clark,⁴ in an address to members of the British Medical Association on this same subject of variability in response, cites other studies, for example of the amount of sodium amylal

Chart 2.—Frequency distribution of individual lethal doses (frequency polygon, below) and the cumulative or integrated frequency of the same doses (above). The smooth curve drawn through the upper blocks is the S shaped or sigmoid curve mentioned in the text. On this curve, the L. D. 50 would correspond to 5 dosage units. This is an idealized experiment.

required to produce analgesia for labor and of evipal soluble for anesthesia, which yield similar curves. The lethal doses of diethylene glycol for human beings, as

4. Clark, A. J.: Individual Variation in Response to Drugs, *Brit. M. J.* 2: 307 (Aug. 14) 1937.

compiled by Calvery and Klumpp,⁵ have a similar distribution. When their data are published there will be available for the first time an L. D. 50 for the human species, or at least a value approaching it. A moment's consideration will reveal why the present lethal doses for man of different poisons given in toxicologies differ so much. They merely represent the results on a few of the members of the group that must be used to give anything approaching an exact value. Put differently, they are definite evidence of the variability that forms the subject of this report.

Recently the extensive use of metrazol for the production of convulsions in human beings has made possible compilation of data. Hitchcock⁶ in my laboratory has shown that the doses required have the typical distribution and yield the sigmoid curve. Further examples need not be given. It is evident from those cited that the variability found by the pharmacologist working in the laboratory with populations as uniform as possible as to sex, weight and nutrition is to be anticipated in the human species. As a matter of fact the lack of uniformity in human populations with respect to age, weight, sex and physical health would lead one to expect an even greater degree of variability. Not a great deal of exact knowledge exists as to the effect of these factors. It has been clearly shown that there are sex differences, as for example in the case of strychnine. Some years ago McGrath showed that it was much easier to produce gangrene of the tail in male rats than in females by the use of large doses of ergotamine. He further noted that injection of theelin protected the otherwise susceptible males.⁷ When differences in age are considered, even the simplest determinations are complicated by variations in weight as well. In the laboratory, dosage is commonly calculated on a weight basis, but evidence for the correctness of this practice is largely wanting. Indeed the studies on metabolism on both laboratory animals and man indicate that, for this particular determination, corrections are more properly made in relation to surface area, which is not a function of weight.

Finally, when one faces the variability introduced by the presence of disease, quantitative studies are almost wholly lacking. There is here an almost unexplored field of pharmacology, which is surprising in view of the immediate significance of the results to therapeutics.

In all this discussion there has been presented nothing that is new. Every physician is aware of course that there exists the type and degree of variation that has been described. Yet there are implications that are not recognized, if one may judge by the questions that come to the pharmacologist from his clinical colleagues. For example, the spread of response described means that any fixed dose system of anesthesia is unsound. If a series is large enough there will inevitably be a number of dangerous or even fatal reactions from what are ordinarily considered safe doses. If normal cats vary as has been described in their susceptibility to digitalis, it is certain that in the administration of massive doses of digitalis for prompt action there will be instances of patients representing the lower part of the curve, poisoned by amounts of digitalis not dangerous to the greater number of patients. If alcoholic intoxication is diagnosed on the basis of blood alcohol alone, some drivers will be charged with a degree of intoxication

that is either greater or less than their degree of motor control justifies. If local anesthetics are injected for surgical operations, an occasional patient will show alarming reactions.

Because one must recognize that variation is a biologic fact, one should not therefore fold one's hands and accept the situation without an attempt at clarification. Even variability must have an explanation. But if the experience of those who work with populations rather than with individuals, under more rigorously controlled conditions than are usually possible in the practice of medicine, can at all be translated into the clinical field, then occasional untoward reactions which are not due to idiosyncrasy or thymicolymphatic constitution or air emboli or improperly prepared solutions are to be anticipated.

CONCLUSION

It is urged that, when the practicing physician is working with material that could be treated by the pharmacologist to gain further insight into the degree and extent of human variability, he should report his data in detail. When more knowledge is available, when the pharmacologist can with some assurance predict the safe ranges in human pharmacology, then perhaps he can at the same time add something to the safety and effectiveness of human therapeutics, which after all is one of his chief reasons for existence.

THE HAZARDS OF FARMING

JOHN H. POWERS, M.D.

COOPERSTOWN, N. Y.

During the past quarter century the hazards of industry, transportation, mining and construction have been recognized; the economic value of safety has become clearly apparent and measures have been adopted to insure its promotion. For agriculture, because of its primarily individualistic character, there has been no such recognition or supervision, and farming, though the oldest occupation in the world, remains the most hazardous.

Having lived and practiced surgery in a rural community during the past eight years, I have become interested in the hazards to which the farmer is daily exposed and the accidents which result therefrom. In central New York, small dairy farms are numerous and farming is often an occupation of necessity rather than choice. Many of the farmers are poor, their equipment is inadequate and frequently out of repair, wages are low and hired help is difficult to find and often incompetent. Because of these circumstances, carelessness and inefficiency are common and serious accidents are prone to occur.

This report is based on a review of 310 accidents of this type sustained in a rural section of New York State. The patients were treated at the Mary Imogene Bassett Hospital in Cooperstown, N. Y., during the years 1929-1938 inclusive.

An analysis of the records has disclosed numerous interesting facts relative to farm injuries which seem pertinent for presentation to the Section on Preventive and Industrial Medicine and Public Health. The only other data on agricultural accidents of which I am aware have been collected by the Kansas board of health from

fatal farm accidents in that state. The statistics herein reported have been compiled from accidents of sufficient severity to necessitate admission of the patient to the hospital or to require major surgical treatment in the operating room.

ANALYSIS OF 310 FARM ACCIDENTS

1. *Incidence, Liability and Seasonal Distribution.*—Many seemingly irrelevant conditions have a direct influence on the admission of patients to hospitals. The

Chart 1.—Seasonal distribution of farm accidents compared with all rural accidents.

economic status of the family, the season of the year, the condition of the roads, the distance to be traversed, the severity of the injury, and the attitude of both the family and the physician all exercise a selective effect on statistics of hospital morbidity in a rural area. Hence

TABLE 1.—Etiologic Analysis of 310 Farm Accidents

Activity	Number	Per Cent
Chores	99	31.9
Logging	66	21.3
Haying	50	16.1
Playing of children	31	10.0
Repair and construction of buildings	22	7.1
Assault or suicide	13	4.2
Others	29	9.4
Total	310	100.0

any discussion of the incidence of farm accidents in a given district on this basis is open to some criticism. With this in mind a simple statement anent the incidence of serious farm injuries in this locality, treated at this hospital, will suffice. During the decade embraced by this study there were 1,329 patients with injuries of comparable severity from all types of trauma; 310 of these, or 23.3 per cent, were related to the hazards of farming.

Of the farm accidents 70.3 per cent were due to carelessness of the person injured and 9.4 per cent to the carelessness of some one else, 15.5 per cent were unpre-

dictable, 4.2 per cent were intentional and in 0.6 per cent the liability for the accident could not be definitely allocated.

Summer is the most dangerous season on the farm; late winter, the most secure. The curve representing the seasonal distribution of all farm accidents (chart 1) is comparable to that for all rural accidents reported at the Conference on Rural Medicine in Cooperstown in 1938.¹ Accidents in the course of routine chores are more or less constant throughout the twelve months; those due to logging occur most frequently during the late fall and winter, while those incidental to haying are naturally much more numerous during July and August (chart 2). The summer peak is composed largely of haying accidents and accidents due to unclassified activities, including the playing of children.

2. *Location.*—Exactly one half of these 310 farm accidents occurred in the barn or barnyard, 13.5 per cent in the woods, 12.6 per cent in the surrounding

TABLE 2.—Etiologic Agents in 310 Farm Accidents

Agent	Number	Per Cent
Tool or implement	56	18.1
Animal	51	16.5
Machine	40	12.9
Vehicle	36	11.6
Falling tree	17	5.5
Heat or Cold	7	2.2
Others or none	103	33.2
Total	310	100.0

fields and pastures, 8.4 per cent in the hayfield and only 6.8 per cent in the house and shed. A few occurred on the highway but were not due to motor vehicles.

3. *Etiology.*—At least two factors participate in the causation of most farm accidents, a motivating activity and a causative agent. Of the former, routine chores accounted for nearly one third of the accidents, logging for one fifth and haying for one sixth (table 1). Ten per cent of the accidents were sustained by children

Chart 2.—Curves representing the seasonal variation of farm accidents and their common motivating activities.

while at play on buildings or vehicles, in trees or near men at work with machinery. Assault or suicide was responsible for 4.2 per cent of the injuries, a rather unexpected hazard but one which may be explained by the lonely life of poverty and solitude which many farmers lead in distinctly rural areas.

1. Powers, John H.: Rural Medicine: Emergency Surgery in a Rural Hospital, Springfield, Ill., Charles C. Thomas, 1939, p. 51.

The etiologic agents are recorded in order of frequency in table 2. Eighteen per cent of the accidents were caused by farm tools or implements, 16.5 per cent by animals, 12.9 per cent by machinery, 11.6 per cent by vehicles, 5.5 per cent by falling trees or rolling logs and 2.2 per cent by heat or cold. Under "others" are included barbed wire fences, rusty nails, splinters, thorns, hooks, chains and firearms. When a fall occurred with no obvious causative agent responsible, none was recorded; the numerous falls on slippery, icy ground account for the high percentage of accidents included in this category.

4. *Distribution by Age and Sex.*—In central New York state all rural accidents were found to be most common between the ages of 15 and 24; males were injured twice as frequently as females.¹ Farm accidents show no such definite peak but occur with little significant variation from the beginning of the second decade throughout the active working life of man. Males are involved with ten times the frequency of females (chart 3).

5. *Analysis of Interval Between Accident and Admission.*—One phase of this study has been of particular interest, namely the disclosure of the length of time required for injured farmers in the surrounding country-

Chart 3.—Distribution of farm accidents by age and sex.

side to reach the hospital after an accident has occurred. The data are presented in chart 4; 30 per cent of the patients arrived within one hour, 46 per cent within two hours, 56 per cent within four hours and 63 per cent within six hours. The percentages for subsequent intervals up to one week are tabulated in the chart.

6. *Classification of Injuries and Topographic Distribution of Injuries and Fractures.*—There were 289 fractures, of which eighty-five were compound, comprising 33.7 per cent of the 864 recorded injuries, classified according to the second edition of the Standard Classified Nomenclature of Disease. Lacerations were next in frequency. Division of nerves, blood vessels and tendons and partial or complete amputations of fingers, hands or forearms are common among farm injuries and are due to contact with rotary saws, mowing machines, ensilage cutters, scythes and axes. Eleven per cent of the patients sustained concussion of the brain, and approximately 6 per cent were in shock on arrival at the hospital. Many patients received multiple lesions of bones and soft tissues in combination. All the injuries are classified by number and percentage in chart 5.

Actually of more interest in a study of the hazards of farming is the topographic distribution of the injuries and fractures thereby sustained. These are presented in chart 6, which shows that, although the shoulder and upper extremity were injured much more often (in approximately 30 per cent of the cases) than the

hip and lower extremity, the bones of these parts were fractured with almost equal frequency.

7. *Period of Hospitalization.*—As a result of these farm accidents 4,855 days were spent in the hospital by 266 inpatients and 1,333 visits were made to the ambulatory surgical clinic by 232 outpatients (chart 7).

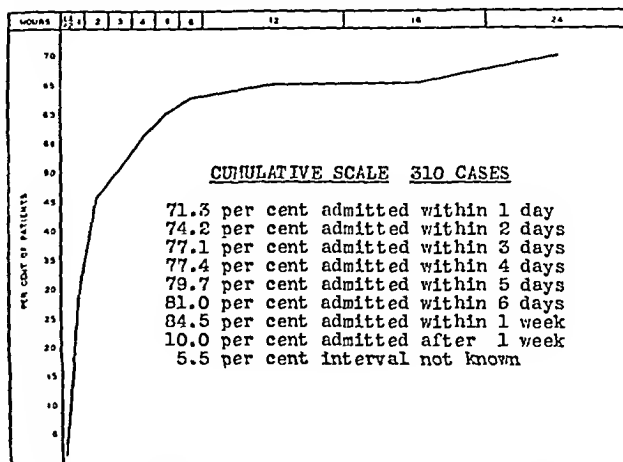

Chart 4.—Analysis of interval between accident and admission.

These figures represent both time which the farmer can ill afford to lose and money which he can even less well afford to pay for hired help. The average period of hospitalization was 18.3 days and the average number of outpatient visits was 5.7, yet neither figure is an accurate representation of the total period of disability.

8. *Fiscal Analysis.*—The actual cost of a serious injury is to most farmers a major financial catastrophe.

Chart 5.—Classification of 864 injuries sustained in 310 farm accidents.

Twenty per cent in this series were able to pay nothing for their professional care and hospitalization, 18 per cent paid in part and 62 per cent paid in full. Most of the last mentioned required many months and even years for the complete discharge of their financial obligation. The hospital was forced to accept a financial

loss of about \$10,000, or 30 per cent of the total charges made for hospitalization, outpatient visits and professional care incidental to the hazards of farming.

9. *Analysis of Fatalities.*—Sixteen of the patients did not survive. Three were moribund on admission and died from the immediate effects of trauma within a few hours. Three lived less than one day, and five survived from two to four days. The remaining five died from

Mortality, 5.1 per cent

ten to fifty-three days after admission because of complications associated with the late effects of trauma or from intercurrent disease. Fourteen of the deaths were of adults, with an average age of 55 years, and two were of children.

The contributing activities and agents are given in order of frequency in table 3. The mortality for the entire group of 310 patients was 5.1 per cent.

SUMMARY

Agricultural accidents were responsible for nearly one fourth of all the serious injuries treated at a medium sized rural hospital in the central part of New York

Chart 6.—Topographic distribution of injuries and fractures due to the hazards of farming. All injuries of each anatomic subdivision are recorded above the horizontal line and in the black columns; all fractures of the bones of the same subdivision are recorded below this line and in the shaded columns.

State during the years 1929-1938 inclusive. Such accidents showed a definite seasonal variation with a peak during July and August, for which haying, the playing of children and other unclassified activities were largely responsible.

Fifty per cent of all farm accidents occurred either in the barn or in the barnyard.

Routine chores were the most dangerous single motivating activity, with logging and haying next in order of frequency. Farm tools and implements, animals, machinery and vehicles all contributed their share of injuries in about equal proportions. Falls were numerous.

Males were involved with ten times the frequency of females.

Nearly 50 per cent of the patients reached the hospital within two hours.

Fractures comprised one third of all injuries; division of nerves and tendons and partial or complete amputa-

Chart 7.—Data relative to period of hospitalization and number of outpatient visits.

tions of fingers and hands were common. The shoulder and upper extremity were injured more frequently than the hip and lower extremity.

The average period of hospitalization was 18.3 days and the average number of outpatient visits was 5.7.

The monetary loss incidental to a serious injury was for most farmers a major financial catastrophe. Twenty per cent were unable to pay anything for their hospitalization and professional care.

The mortality was 5.1 per cent.

CONCLUSION

Farming is an exceedingly dangerous occupation, the hazards of which are not universally appreciated.

ABSTRACT OF DISCUSSION

DR. FRED P. HELM, Topeka, Kan.: It is fitting that a physician devoted to the conservation of human life has made this study. Farming is the occupation in which more accidents occur than in any other line of industry, and it is the occupation in which the least accident prevention effort has been made. Education is the chief weapon by which we may combat farm accidents, and a study of the causes is essential as the basis of a safety program. The causes of farm accidents, as stated by Dr. Powers, include machinery, animals, vehicles and falls. These causes tally with the experience of the Kansas State Board of Health. There is some variation in Dr. Powers' analysis, as compared to the data assembled in our office, which may be accounted for by the fact that (1) Dr. Powers' study includes nonfatal as well as fatal injuries, whereas our figures deal only with fatal accidents; (2) Dr. Powers has included all persons dwelling on the farm, whereas the health department classification includes only those engaged in agriculture; (3) Dr. Powers has included under "farm" accidents injuries which, in our records, fall under four classifications, namely "home," "motor vehicle," "public" and "occupational," and (4) homicidal or suicidal injuries are not classified as accidental by vital statistics bureaus. Obviously, restricting farm injuries to those incurred in agriculture would change the picture as to cause, age and sex. It is characteristic of all accident injuries,

however, that far more occur in males than in females. The reports coincide in that summer is the season of greatest frequency. Deaths due to Kansas farm accidents, by cause, during 1930-1938 inclusive, were machinery 244, animal 171, excessive heat eighty-nine, vehicular eighty-one, falls eighty, lightning forty-three, puncture and incised wounds and abrasions forty-two, injury by falling trees cut for firewood or posts thirty-eight, burns twenty-one, falling objects (other than trees) eight, excessive cold seven, electric shock five and "other" twenty-five, a total of 854. Although the leading cause is machinery, as one would expect in this "mechanized" age, the animal injuries, plus those caused by horse-drawn vehicles, exceed the machinery fatalities. Dr. Powers stated that "70 per cent of farm accidents are due to carelessness." Our reports also prove carelessness to be the leading cause. These accidents therefore are largely preventable.

DR. A. G. CRANCH, New York: Dr. Powers has emphasized certain hazards well worth considering. One is accustomed to overlook the hazards in farming and agriculture. I spent practically five years in a rural community without hospital facilities or improved roads or automobiles, and I have a little different point of view from the men in the hospitals. Such a hazardous situation exists in farming because of the primitive, makeshift tools usually employed for the work on the farm, because of the improper use made of ill adapted tools and because the machinery on the farm is almost completely unguarded. The safety movement as we know it in industry is practically unheard of in farm circles, and you can't tell them; they know! Their fathers did it that way before them, and their grandfathers did it that way even before them, and why should they change their methods? The missionary work I accomplished in five years was practically nil. The accidents went on and from the same sources, because of primitive instruments and unguarded tools. There are two other features in connection with rural hazards. One is the presence of infections, the other infectious diseases. Tuberculosis I found far more prevalent than one would expect in the rural community. Other conditions peculiar to farming, especially around the threshing season, are respiratory infections, fungous infections, allergic conditions and the like. Another thing rather noticeably frequent in rural areas was the presence of psychiatric conditions resulting possibly from isolation and monotony more than anything else. The mental conditions seemed out of proportion to the population.

DR. LEOPOLD BRAHDY, New York: In New York we have long been considering the advisability of extending compensation laws to the farming community and it is only with the data in such papers as we have just heard that one can deal with that question intelligently. There are several things I would like to hear more about. One of them is brought up by the surprisingly small, 2 per cent, number of injuries due to cold. When we have a snowstorm in the city and put thousands of men to shoveling snow, we have scores of serious frostbites, largely because these men are not used to working in the cold. How many of these farm accidents do you estimate occur to the hired help, who are incompetent because they are not used to farm life, and how many occur among the farmers themselves? The effect on the farmer's economic status when he has a serious accident must be given a great deal of consideration from a social and public health point of view, from the standpoint of the individual who is injured, and from the point of view of our own profession. On this important subject there are so little data that this excellent paper marks, I hope, the beginning of a great deal of study along this line.

DR. JOSEPH W. MOUNTIN, Washington, D. C.: The section is deeply indebted to Dr. Powers for this splendid paper. There are at least three reasons why accidents constitute a public health problem: Accidents are a major cause of death and of disability; they are preventable in large part; health agencies are equipped for organizing measures in accident control. Accidents of the type described by Dr. Powers come within the province of health departments. No other agency is so well prepared by reason of its interest and the techniques represented in its staff as an organized county health department for resolving the causative factors associated with farm and home accidents. In the way of specific procedure, I make these suggestions: The health department should endeavor to secure

reports on accidents—those of a minor character as well as the ones that have come to medical attention. The circumstances associated with each accident should be investigated by the health officer, the nurse or the sanitation officer. Moreover, routine inspection of premises may disclose hazards that have not as yet given rise to accidents. Many hazards about the farm could be corrected by rather simple alterations of building and grounds. Improvement in the design of farm machines offers another possibility. Perhaps the largest achievements will come as a result of education. Habits of safety need to be inculcated. Most of all, farmers should be impressed with the fact that they live and work in a dangerous environment. I urge that the health authorities become active workers in the safety movement and most especially in that part of it which is concerned with prevention of farm and home accidents.

DR. J. N. BAKER, Montgomery, Ala.: I too should like to commend Dr. Powers for the lucid and painstaking manner in which he has presented his personal observations and study on the hazards of farming. To an administrative health official of Alabama, which is still predominantly rural, the questions discussed have an added importance. Because of the necessity for concentration in our state on certain major health problems arising from environmental conditions such as malaria, hookworm and pellagra, and which, through an organized health machinery, are being brought under control, the hazards of the farm worker, as contrasted with the industrial worker, have as yet claimed small attention. The educative implications of this study seem clear: agricultural states, under the leadership of their health departments, must seek to bring to their rural population every possible safeguard against hazards, just as our industrial hygiene units are striving to protect the employee in the factory. The "safety first" doctrine, so valuable to industry, must be made to permeate our rural workers. Here is a comparatively new "preventive field" opening up which challenges the resourcefulness alike of physicians and of health workers. Because of the economic factors which figure in the proper medical and hospital care of farm workers after the accident has happened, I should like to have Dr. Powers outline the economic status of this group; that is, how many may have been on relief or were clients of the Farm Security Administration or, through any source whatever, may have had protection through accident or indemnity insurance.

DR. JOHN H. POWERS, Cooperstown, N. Y.: With regard to Dr. Helm's comment about assault and suicide, I appreciate the fact that these are not accidents but, nevertheless, I do regard them as definite hazards of farming in a distinctly rural area and for that reason they were included. Women are involved in agricultural accidents more frequently in central New York State than in Kansas, primarily because of the difference in the type of farming. Where every member of the family must do some form of agricultural labor, carelessness and inefficiency are common; individuals of both sexes and all ages are prone to injury. Dr. Cranch has certainly lived in a rural community. The fact that farming has been done in the same way for generations is undoubtedly responsible for many of these accidents. It is difficult to educate the farmer along progressive lines. Dr. Brahdry's comment regarding the small number of injuries or accidents due to cold can be explained by the fact that the farmer dresses properly for cold weather and the urban citizen does not. With reference to Dr. Mountin's remarks, much, I am happy to say, has been done in a general way regarding the prevention of farm accidents, particularly by two great organizations, the American Red Cross and the National Safety Council. For three years the Red Cross has been interested in this problem and through its local chapters has been directing a program to promote greater safety on the farm and in the home. With regard to Dr. Baker's remarks, I did analyze these statistics from a fiscal standpoint. Sixty per cent of the patients were able to pay in full for their period of hospitalization, professional care and outpatient visits; 20 per cent were able to pay in part, frequently a very small part, and 20 per cent paid nothing. A serious injury is to most farmers a major financial catastrophe; months and even years are required for the complete discharge of the debt thus incurred. Certainly less than 10 per cent of farmers carry accident insurance or any other type of protection, and, even when carried, the amount is usually very small.

THE DELAYED APPEARANCE OF HEART DISEASE AFTER RHEUMATIC FEVER

EDWARD F. BLAND, M.D.

AND

T. DUCKETT JONES, M.D.

BOSTON

Involvement of the heart can be recognized in approximately 70 per cent of patients during the course of rheumatic fever in childhood¹ (table 1). It is generally believed that the remaining 30 per cent also have at the same time minimal cardiac damage too slight to be evident by present methods of clinical study. The later appearance during subsequent years of characteristic signs of permanent valvular deformity in a considerable number of the latter group lends support to this conception. This delayed appearance of heart disease is responsible, however, for one of the chief elements of uncertainty with which these patients with so-called potential rheumatic heart disease must contemplate the future. This uncertainty is due in part, we believe, to

a lack of information concerning the actual incidence and the extent of this later, and often insidious, crippling of the heart.

Continuity of observation based on the entire life span of a large number of patients with potential rheumatic heart disease in different sections of the country will be necessary for conclusive data. It is evident, however, that studies of such duration lie in large measure outside the scope of contemporary medical experience; nevertheless, we believe that it may be helpful to present at this time certain interval data relevant to this difficult clinical problem.

CLINICAL OBSERVATIONS

The source of our material has been described briefly in previous communications. Since 1920 (a period of nineteen years) approximately 1,700 children and adolescents with rheumatic fever or chorea have received prolonged care and intensive study at the House of the Good Samaritan during an active stage of their disease.

From the House of the Good Samaritan.

The expenses of this study have been defrayed by a grant from the Commonwealth Fund.

Read before the Section on Practice of Medicine at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

Schlesinger, Bernard: Public Health Aspect of Heart Disease in Childhood, *Lancet* 1: 593 (March 12) 1938. Bland, E. F., and Jones, T. Duckett: Unpublished observations, 1938.

In the majority it represented the initial attack, and the average age at the time of the original illness was approximately 8 years. The average period of hospitalization has been from three to four months, and not infrequently as long as from one to two years. A further and an important aspect of this study has been the subsequent observation at frequent intervals of the majority of this group. We ourselves have done the greatest portion of this follow-up study.

From this group of 1,700 patients, only those on whom we have complete data for a full ten years (or more) have been considered suitable for our present purpose. They constitute a special group, 1,000 in number, which will serve as the basis for a comprehensive ten year report now in preparation. Among this group of 1,000 young patients there were 314 (31 per cent) who on recovery from their initial rheumatic infection were left without demonstrable damage to the heart. The subsequent course of these 314 patients with potential rheumatic heart disease serves as the basis of this report.

The Delayed Appearance of Rheumatic Heart Disease.—In table 2 we have indicated the subsequent cardiac status to date for these 314 patients. It is to be noted in this table that the data are complete on the entire group for the first two five year periods after the onset of their rheumatic fever. A considerable number (153)² have also been followed into the second decade. Our present observations must necessarily be confined to the completed decade. There are, however, certain trends already evident in the second ten year period suggestive of the future course of events and, hence, important for our present consideration.

The completed decade covers for the majority of these patients the years from 8 to 18. This in turn embraces the most unstable period in the natural course of their disease—represented on the one hand by the high incidence of recrudescences and fatalities during these early years³ and on the other by the regression of physical signs of cardiac involvement (enlargement and murmurs) in many instances, and complete disappearance in others.⁴

Signs of permanent valvular deformity have appeared to date in seventy-nine patients (25 per cent of the original 314). In approximately two thirds of these seventy-nine patients (fifty-five in number) a recrudescence of rheumatic fever or of chorea was recognized at the time of this later appearance of heart disease. In the remaining one third (twenty-four patients) signs of valvular deformity appeared insidiously without other clinical evidence of coexisting rheumatic activity.

The importance of the first ten years in the natural course of rheumatic fever and rheumatic heart disease already noted is further emphasized by the after-history of this special group. In only five patients have the signs of heart disease appeared to date after this first ten year interval; in two instances with coexisting signs of rheumatic activity, and in three instances without such being recognized. This represents a striking contrast to the number (seventy-four patients) in which the delayed signs of heart disease appeared during the first decade. It seems unlikely that this considerable difference is to be entirely accounted for by the fact that

2. This group of 153 patients shown in table 2 is composed of thirty-eight in whom heart disease had appeared during the preceding decade, four in whom heart disease appeared from ten to fifteen years after the onset of rheumatic fever, and 111 still without signs of heart disease.

3. Bland, E. F., and Jones, T. Duckett: Fatal Rheumatic Fever, *Arch. Int. Med.* 66: 161 (Feb.) 1938.

4. Bland, E. F., and Jones, T. Duckett: Disappearance of the Physical Signs of Rheumatic Heart Disease, *J. A. M. A.* 107: 569-572 (Aug. 22) 1936.

the data are as yet complete on only one half of the original 314 patients for the third five year period.

The twenty-four patients in whom heart disease became evident without evident coexisting clinical signs of rheumatic activity are of special interest. The appearance of valvular deformity in twenty-one of these twenty-four patients during the first ten year period when rheumatic fever is known to be most active strongly suggests that in this "rheumatically" silent group the insidious appearance of valvular disease also coincides with subclinical activity of the rheumatic process. The later occurrence of clearly evident rheumatic fever in eleven of the twenty-four patients lends further support to this interpretation.

Manifestations of Rheumatic Fever.—The manifestations of rheumatic fever in this special group of seventy-nine patients has followed the general pattern of rheumatic fever in our larger series of 1,000 patients. In the majority, however, it has been mild. The initial attack was considered severe in only seven instances. In four additional patients, although the antecedent rheumatic fever had been mild, the later appearance of heart disease coincided with a severe recrudescence. In fourteen additional patients rheumatic fever was of average intensity, but in the remaining fifty-four it was of a decidedly mild order.

Chorea has been a prominent clinical manifestation. It occurred in sixty-four patients (81 per cent), which is a significantly higher incidence than in our larger series of 1,000 patients (50 per cent). In the majority (thirty-eight instances) it was clearly associated with other clinical or laboratory signs of coexisting rheumatic infection; in four patients other evidence of rheumatic activity in addition to chorea occurred after the signs of heart disease had been noted. In the remaining twenty-two instances no indication of rheumatic activity other than chorea could be identified either before or after the appearance of heart disease.

In a previous communication we presented evidence which led us to believe that chorea more often than not occurred as a manifestation of a relatively mild form

of the opinion, previously expressed, that although "pure" chorea is still considered by us a manifestation of rheumatic fever it represents as far as the heart is concerned a relatively mild form of the disease.

A further indication of the relative mildness of the preceding rheumatic fever in this special group is the absence of significant cardiac enlargement in the majority. In sixty patients (76 per cent) there remains either none or, at most, only slight residual enlargement

of the heart. Auscultatory evidence, however, of deformity of the mitral valve is present in seventy patients, in forty of whom aortic regurgitation is also present. The involvement of the aortic valve is of slight degree in the majority, but peripheral evidence of free regurgitation is present in six instances. In the remaining nine patients aortic regurgitation of slight degree has occurred without definite signs of coexisting involvement of the mitral valve. Aortic stenosis has not yet appeared in this group. In general, the structural alterations in the heart to date have been slight and the impairment of cardiac function minimal. Eleven patients have died. A recrudescence of rheumatic fever was responsible for congestive heart failure and death in ten instances. The remaining patient died suddenly and unexpectedly.

Recurrent Rheumatic Fever and the Later Appearance of Heart Disease.—The unfavorable effect on the heart of recurring rheumatic activity is well shown in table 3. Of the 132 patients who survived their original illness with no demonstrable cardiac involvement and have continued without subsequent rheumatic fever or chorea, only eight (6 per cent) have had signs of valvular disease appear, whereas, in the remaining 182 patients who have experienced recurring episodes of rheumatic activity, signs of valvular deformity have appeared in seventy-one (39 per cent).

COMMENT

The incidence of heart disease appearing later in our series of 314 patients is notably higher than that recently recorded by Boone and Levine.⁶ These observers found that among 166 patients with potential rheumatic heart disease only 4.8 per cent subsequently developed signs of valvular deformity. Their period of observation averaged 9.6 years for the group. This compares with an incidence of 25 per cent in our patients, all of whom have been followed for ten (or more) years. We are of the opinion that this considerable difference in the incidence of heart disease in the two series is to be accounted for by certain important differences in the material studied. It must be remembered that the majority of our patients at the onset of their rheumatic

of rheumatic fever.⁵ This conception was based in part on the lower incidence of heart disease in those patients whose rheumatic fever was manifested, among other signs, by chorea than in those with rheumatic fever not associated with chorea. This lower incidence of cardiac involvement was especially striking in the so-called pure chorea group. The late appearance of permanent valvular deformity in a few additional members of this uncomplicated chorea group strengthens

fever were approximately 8 years of age, whereas the average of the group studied by Boone and Levine was 13.8 years when first seen by them and hence already well along in the decade in which rheumatic fever is known to be most damaging to the heart (namely, from 5 to 15 years of age). We are inclined to accept this apparent discrepancy in these two well studied groups as important additional evidence bearing on the natural course of rheumatic fever in young people. It emphasizes again the already well recognized significance of the events in the earliest years after the onset as most important in determining the subsequent extent of residual cardiac damage.

It remains to be seen how many of those who at present continue without evident heart disease will in later decades develop signs of stenosis of the mitral or aortic valve. The experience of Boone and Levine with the intermediate age group, as well as our own observations on the younger patients already followed into the second decade, are encouraging. A sharply diminishing incidence in the later appearance of valvular disease is to be expected. This prediction is in accord with other recognized features of the natural course of rheumatic fever and of rheumatic heart disease.

It should be emphasized that, although the data here presented concern an unfavorable development in the course of rheumatic heart disease from childhood through adolescence, one must not lose sight of the more favorable course of others. From the broader perspective of the after-histories in our ten year group of 1,000 patients, those in whom heart disease has later developed have been more than balanced by an equal number in whom the signs of heart disease have regressed and ultimately disappeared.

CONCLUSIONS

From a ten year follow-up study of 314 children and adolescents with potential rheumatic heart disease it has been shown that:

1. Characteristic signs of permanent valvular deformity not present at the time of the original illness have appeared later in seventy-nine patients (25 per cent).
2. This so-called delayed appearance of heart disease was clearly associated with coexisting signs of recurrent rheumatic fever in two thirds of the group.
3. In the remaining one third it appeared insidiously. Certain evidence suggests that here also the appearance of the signs of heart disease coincides at this age with persistent subclinical rheumatic activity.
4. Further observation into the second decade indicates that a sharply diminishing incidence in the later appearance of heart disease is to be expected in the remainder.

25 Binney Street.

ABSTRACT OF DISCUSSION

DR. HELEN B. TAUSSIG, Baltimore: This paper has emphasized the late manifestations of rheumatic heart disease. The important feature, it seems to me, is not the number who develop heart disease but the number who escape without cardiac damage. The authors' figures show that only 25 per cent of patients who give no evidence of cardiac damage after their first attack have subsequently developed rheumatic heart disease; of those 25 per cent in only one third did heart disease develop insidiously. I should like to ask Drs. Bland and Jones whether they do not believe that the development of rheumatic heart disease is an indication that these patients are suffering from persistent active infection; in other words, that rheumatic heart disease is not the late result of a former attack but that it is, in itself, an indication of a subclinical attack.

In our clinic we have been impressed by two groups: First, the group who do not report to clinic with the mild illnesses. The second, those who report to the clinic with no complaints but who show a low grade fever and change in quality of heart sounds or in the type of murmur. I believe that such manifestations are indicative of an active infection; in the vast majority of these cases the sedimentation rate has been found to be accelerated. I believe that changing endocardial murmurs indicate an active rheumatic infection. The authors' analysis of single and multiple attacks seems to me highly significant in that the number who have developed chronic rheumatic hearts following a single attack is only about 8 per cent, whereas among those who had multiple attacks it was 39 per cent. This indicates that those who do not have obvious clinical manifestations are much less liable to have subclinical manifestations of disease. I should like to ask about the group of four cases in which signs of heart disease developed ten or more years after the original attack. Did these patients have single or multiple attacks? Did the authors think these cases of heart disease represented the end picture of the early infections or were they reinfections? I concur with the idea that these patients who had little or no cardiac enlargement suffered from mild rheumatic infections. In my opinion, cardiac enlargement is not a late result of previous valvular lesions but is primarily due to myocardial damage.

DR. T. DUCKETT JONES, Boston: I should like to stress one or two general features which Dr. Bland referred to in the series which he reported. The incidence of the late development of rheumatic heart disease is 7.9 per cent of a group of 1,000 patients, followed for a period of ten years. There was a regression or disappearance of the signs of heart disease in about the same percentage of those patients who developed rheumatic heart disease early in the course of their rheumatic fever. The two groups roughly balance each other. Improvement is chiefly due to a lack of recurrences of rheumatic fever. The question of active rheumatic fever is the most pertinent and important feature in determining the outcome in a given rheumatic subject. I know of no more difficult problem than the evaluation of therapy in a disease the cause of which is unknown, and one for which there is no specific diagnostic test. The disease can be diagnosed only by the presence of a more or less clearcut clinical picture or by the resultant rheumatic disease. It is comparable to tuberculosis. I know of no series in which has been proved with adequate controls that long rest and sanatorium care have been the controlling factor in the tuberculosis situation. It seems rational that in caring for patients who have a chronic disease lasting for months, and sometimes years, punctuated by repetitive acute illnesses, usually precipitated by acute respiratory infection, we should give the patient the benefit of perhaps one of the most important laws of nature, namely, rest. I know of no other real reason why we should keep these patients down other than the fact that by taking them out of circulation it removes them from contact with those factors or agents that frequently cause their disease to increase in severity. From the results of our ten years of observation it has been found that 60 per cent of the rheumatic patients who have been given long bed care during active infection are leading normal lives today. About half of these have slight rheumatic heart disease and the other half have no clinical evidence of heart disease. Of the remaining 40 per cent, about 25 per cent die. The remaining 15 per cent enter adult life with moderate to severe rheumatic heart disease and have either moderate or considerable restriction of their physical activities. This 15 per cent represent rheumatic heart disease as it is seen in the adult cardiac clinics and in the wards of the general hospitals.

DR. EDWARD F. BLAND, Boston: We believe, although not yet able to prove it, that the rheumatically "silent" group of patients who develop signs of heart disease represent subclinical rheumatic activity. We have had occasion to follow closely patients who were developing signs of mitral disease without other signs of rheumatic activity at the time. In some instances we were not able to establish clearly an active process by our usual criteria, and yet we felt certain that the rheumatic process was active in the heart. As to the second

question concerning the small group of five patients who, after a latent period of ten or more years, developed signs of heart disease; they were all patients who had in the interim recurring episodes of rheumatic activity. I should like to add one word concerning the effects of pregnancy. Dr. B. J. Walsh has recently reviewed our data in this connection, and he agrees that the majority of these patients, with but few exceptions, go through pregnancy later on without difficulty.

RECURRENCE OF OTITIC INFECTIONS DUE TO THE BETA-HEMOLYTIC STREPTOCOCCUS

FOLLOWING INADEQUATE SULFANILAMIDE THERAPY

JOHN MARQUIS CONVERSE, M.D.

NEW YORK

The extraordinary success of sulfanilamide in the treatment of streptococcal otogenic meningitis has led to the widespread use of the drug in all cases of otitic infection in which the beta-hemolytic streptococcus can be identified. Such enthusiasm for specific chemotherapy is readily understood but is open to considerable criticism. The patient with meningitis is under hospital observation, and treatment is continued until the spinal fluid has returned to normal. The patient with acute otitis media or mastoiditis receives sulfanilamide only as long as there is persistent pain or discharge, and treatment is usually stopped on clinical instead of laboratory evidence.

It has been shown that the sulfanilamide treated animal survivors of hemolytic streptococcus infection fail to acquire protective antibodies as a result of their experience.¹ Lyons² has demonstrated that sulfanilamide induces an attenuation of the virulence of hemolytic streptococci and that the organisms regain their virulence on subcultivation in the absence of sulfanilamide. He has further shown that antibacterial antibody is an important adjunct to sulfanilamide therapy. These facts are important because they demonstrate that inadequate sulfanilamide therapy or premature discontinuance of the drug may permit the infecting streptococci to become fully virulent again in a patient who has no immunity to his infection.

My purpose in this report is to present a series of cases in which it appears likely that the premature cessation of sulfanilamide therapy was followed by recurrence and extension of the original infection.

BACTERIOLOGIC ANALYSIS OF ACUTE SUPPURATIVE OTITIS MEDIA AND SUBSEQUENT MASTOIDITIS

Table 1 demonstrates that only a small percentage of patients with acute suppurative otitis media progressed to mastoiditis, but it is also apparent that the beta-hemolytic streptococcus was present in approximately

half of the cases. The high incidence of streptococci in cases of otitic infection is adequate reason to attempt a clinical evaluation of the usefulness of sulfanilamide in such cases.

RECURRENCE OF ACUTE SUPPURATIVE OTITIS MEDIA AFTER TREATMENT WITH SULFANILAMIDE

In a number of cases of acute streptococcal otitis media, treatment consisted of paracentesis followed by the administration of 16 Gm. of sulfanilamide in divided doses over a three day period. In some of these cases a recurrence of the acute infection was observed on withdrawal of the drug.

The following four cases are reported from the Baby Clinic of the Massachusetts Eye and Ear Infirmary:

CASE 1.—R. S., aged 26 months, who weighed 35½ pounds (16 Kg.), Nov. 15, 1937, had a rectal temperature of 101.2 F. and a paracentesis was performed for suppurative otitis media on the right side. November 17 the rectal temperature was 100 F. and the right ear was draining well. The left drum was red and bulging; paracentesis yielded pus. November 19 a culture of material from the left ear showed hemolytic streptococci. Both ears were draining well. Sulfanilamide was given, 20 grains (1.3 Gm.) the first day, 15 grains (1 Gm.) the second day and 10 grains (0.6 Gm.) the third day. November 24, the condition in both ears was definitely resolving. The discharge had practically ceased.

November 27 the rectal temperature was 104.4 F. The night before, five days after cessation of sulfanilamide therapy, the discharge had reappeared in great abundance from the right ear. Pain was noted in the left ear. Examination disclosed that the right ear was discharging abundant thick yellow pus through

TABLE 1.—*Bacteria Involved in Acute Otitis Media and Incidence of Complicating Mastoiditis**

	Oct., Nov., Dec. 1937	Jan., Feb., March 1938
No. of cases of acute otitis media.....	100	100

No. of cases of mastoiditis.....	4	5
Beta-hemolytic streptococci.....	2	3

* Statistics for October-December 1937 collected by author; statistics for January-March 1938 collected by Dr. J. C. Crooker.

the paracentesis opening. The left drum was red and bulging, with closure of the paracentesis incision; paracentesis was performed. December 1 the rectal temperature was 99.4 F. The right ear showed no evidence of resolution and no definite postaural signs, but roentgenograms, interpreted by Dr. A. S. MacMillan, revealed "early decalcification" of the mastoid. The condition in the left ear appeared to be resolving quickly, and the landmarks were returning. Sulfanilamide was administered, 15 grains the first day, 10 grains the second day and 7½ grains (0.5 Gm.) the third and fourth days. December 6 the landmarks were returning on both drums. December 10 there was continued improvement.

December 15, nine days after the cessation of sulfanilamide therapy, the right ear began to discharge abundantly through an anterior-inferior perforation. Beginning December 20 sulfanilamide was administered, 30 grains (2 Gm.) the first day, 20 grains the second day, 15 grains the third day and 10 grains the fourth day. The discharge was still abundant. December 23 there was a marked decrease in the discharge, which was becoming mucoid. December 31 there was complete resolution. All landmarks returned.

CASE 2.—L. L., aged 2 years, who weighed 36 pounds (16 Kg.), Dec. 13, 1937, had bilateral paracentesis for acute suppurative otitis media. December 16 the child was brought back to the hospital, the cultures showing hemolytic streptococci. Sulfanilamide, 25 grains (1.6 Gm.), was given. December 17 a marked decrease in the aural discharge was noticed. The

This work was undertaken in the Mosher Laboratory and the Massachusetts Eye and Ear Infirmary, Boston.

Dr. Champ Lyons revised this paper. The antibody and sulfanilamide determinations were done in his laboratory at the Massachusetts General Hospital.

Read before the Section on Laryngology, Otology and Rhinology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

administration of sulfanilamide was continued, 20 grains being given the first day, 15 grains the second day and 10 grains the third day. December 20 the left ear showed a small amount of pus exuding through a small posterior-inferior perforation. December 23 the condition of the left ear appeared to be resolved and the right ear began to show a return of the landmarks.

December 27, seven days after cessation of sulfanilamide therapy, both ears presented an abundant purulent discharge. December 30 the discharge was increasing. Sulfanilamide was again administered, 25 grains the first day, 20 grains the second day, 15 grains the third day and 5 grains (0.3 Gm.) the fourth day. Jan. 3, 1938, the condition in both ears was resolving. January 6 resolution was complete.

CASE 3.—R. C., aged 6 years, who weighed 54 pounds (24 Kg.), Jan. 17, 1938, had a rectal temperature of 100.8 F. and paracentesis was done for suppurative otitis media on the right side. The child presented acute rhinitis and pharyngitis. January 20 he was brought back complaining of pain in the right ear. The culture in the meantime had been reported to show hemolytic streptococci. The paracentesis incision was open. Sulfanilamide was given, 45 grains (3 Gm.) the first day and 30 grains the second day. January 22 the rectal temperature was 99.4 F. The ear had stopped discharging the previous day, the acute rhinitis and pharyngitis had cleared up and for the first time the child slept throughout the night without complaining of pain. The condition in the right ear appeared to be resolving. Sulfanilamide, 20 grains a day, was administered for two days. January 24 resolution appeared complete.

February 14, twenty-one days after cessation of the sulfanilamide therapy, the child had a rectal temperature of 100.2 F. and again complained of pain in the right ear. The drum appeared thickened, with injection of the malleus handle. February 17 the rectal temperature was 100.2 F. and the patient complained of pain in the left ear and increased pain in the right ear. Examination revealed slight fullness and diffuse injection of the left drum; on the right drum the landmarks could hardly be determined. Instead of a paracentesis, sulfanilamide was prescribed; 45 grains was given the first day and 30 grains the second day. February 19 the temperature was 99 F. The child was much improved, and all landmarks could be made out. There was slight thickening in both drums. Sulfanilamide, 20 grains, was given for three days. February 23 the condition in both ears was resolved.

CASE 4.—J. B., aged 5, who weighed 36¾ pounds (16.7 Kg.), Jan. 31, 1938, had a rectal temperature of 100.4 F. and paracentesis was performed for suppurative otitis media on the right side. February 4 the rectal temperature was 99.8 F. and there was a pulsating discharge from the paracentesis incision. Culture showed hemolytic streptococci. February 9 the rectal temperature was 99.4 F. The condition appeared about the same in the right ear. For the past two days the child had complained of pain in the left ear. The left drum appeared injected and thickened, with a slight bulging of the posterior quadrants. Sulfanilamide, 30 grains, was prescribed. February 10 the temperature was 99.6 F. and the condition unchanged. Sulfanilamide, 15 grains, was given. February 11 there was great improvement. The child had had no symptoms, and the condition of both drums was resolving. Sulfanilamide was administered, 10 grains the first day and 5 grains the second and third days.

February 16, three days after the cessation of sulfanilamide therapy, the rectal temperature was 100.4 F., and that night pain began in the right ear. The next day a discharge appeared and the right drum was bulging and injected. The condition in the left drum was resolved. Paracentesis of the right drum yielded pus. February 17 the rectal temperature was 99 F., and there was a pulsating discharge from the paracentesis incision in the right ear. Sulfanilamide, 20 grains, was administered. February 18 the rectal temperature was 99.2 F. and the child felt better. There was a pulsating discharge, with tenderness over the antrum on the right side. Roentgenograms, interpreted by Dr. A. S. MacMillan, showed "decalcification throughout the right mastoid." March 4 simple mastoidectomy on the right side showed that all the cells were broken down. Recovery was uneventful.

Table 2 summarizes the pertinent data with regard to these recurrences following sulfanilamide therapy. It is felt that the patients received too little of the drug for too short a time. Attention is called to the fact that these doses of sulfanilamide were given in the clinical belief that a small amount of the drug would aid the patient in his attempt to overcome the infecting organisms, but it is obvious that apparent recovery was not maintained after omission of sulfanilamide.

THE LATE OCCURRENCE OF MENINGITIS IN PATIENTS TREATED WITH SMALL DOSES OF SULFANILAMIDE AFTER MASTOIDECTOMY

The three patients in this series were all admitted to the hospital during July 1938.

CASE 5.—B. K., a girl aged 6 years, admitted to the hospital May 19, 1938, with suppurative otitis media on the left side of four and a half weeks' duration, had a rectal temperature of 99.6 F., a pulse rate of 100, a respiratory rate of 24 and a white cell count of 8,300, with 58 per cent polymorphonuclears. A history was obtained that the ear had begun to discharge spontaneously after an attack of influenza. The child had no other complaints.

TABLE 2.—Recurrence of Acute Streptococcal Otitis Media in Children Following Small Doses of Sulfanilamide

Case	Diagnosis	Age	Sulfanilamide		Days of Recurrence*	Final Sulfanilamide		Length of Illness, Days
			Days	Total Dose, Gm.		Days	Total Dose, Gm.	
1	Acute suppurative otitis media.....	26 mo.	3	2.8	5	1	4.8	47
2	Acute suppurative otitis media.....	24 mo.	3	4.5	7	1	4.3	25
3	Acute suppurative otitis media.....	6 yr.	4	7.4	21	5	8.6	38
4	Acute suppurative otitis media.....	5 yr.	3	3.4	3	31+

* The number of days elapsing after cessation of the sulfanilamide therapy.

The drum of the left ear was thick, with an anterior-inferior perforation; there was a pulsating mucopurulent discharge, and the canal wall appeared to be sagging slightly, but no postaural signs were found. The roentgenograms, interpreted by Dr. A. S. MacMillan, showed "decalcification throughout" the left mastoid. The tonsils had been removed, and palpation revealed a small mass of adenoids in the nasopharynx.

May 21 a report was obtained that the culture of the pus from the left middle ear showed beta-hemolytic streptococci. May 23 sulfanilamide therapy was started; 50 grains (3.2 Gm.) was given the first day, 30 grains the second day and 15 grains each day thereafter. May 25, two days after the sulfanilamide therapy was begun, a simple mastoidectomy was performed on the left side. The mastoid was found to be broken down, especially around the antrum, and to contain pus throughout. No dura or sinus was exposed. Culture showed no growth. June 6 the child was discharged to the outpatient department for dressings, the middle ear being dry and the postaural wound healing well. The sulfanilamide therapy was discontinued.

June 27 the rectal temperature was 103.6 F., the pulse rate 88 and the respiratory rate 30 and the child was readmitted to the hospital. Two days previously she had complained of frontotemporal headache on the left side, which had recurred persistently, increasing in severity; it had kept her awake at night and had made her scream with pain. That day she had presented nausea and vomiting. On admission she was semicomatose. The right middle ear was normal, the left middle ear was dry and the postaural wound on the left was discharging.

thick pus. Moderate injection of the throat was found. The eyes, including the fundi, appeared normal. The neck was stiff, Kernig's sign was present and Babinski's sign was absent. Lumbar puncture showed an initial pressure of 700 mm., normal dynamics, ground glass fluid, and 16,248 cells, with 99 per cent polymorphonuclears. A blood count revealed 32,000 white cells, with 89 per cent polymorphonuclears, and 3,640,000 red cells.

June 28, at 3 a. m., a revision of the left mastoid and decompression were done. Infected granulations were removed; the tegmen was soft and necrotic, there was wide decompression and the dura was injected and covered with a fibrinous exudate. The sinus was exposed in its full length; the wall was gray and covered with a fibrinous exudate. A culture of material from the mastoid showed hemolytic streptococci, as did a culture of the spinal fluid; culture of the blood was negative. Sulfanilamide therapy was started immediately after the operation. The patient was seen in consultation with Dr. Lyons, who advised the securing of a blood level of sulfanilamide of 15 mg. per hundred cubic centimeters. An antibody determination was performed by Dr. Lyons, who found the phagocytic activity to be 12-28 per cent (twelve cocci phagocytized by 28 per cent of twenty-five cells counted). The child was therefore considered as having practically no bacterial antibody. The blood sulfanilamide level was therefore put up to 25 mg. per hundred cubic centimeters (July 1). The patient's condition improved rapidly.

July 2 the first negative report from culture of the spinal fluid was received. The number of cells in the fluid had dropped from 16,248 to 440, with 56 per cent polymorphonuclears. The white blood cell count had dropped from 32,000, with 89 per cent polymorphonuclears, to 21,000, with 92 per cent polymorphonuclears. The rectal temperature was 101 F. July 6 the reports from culture of the spinal fluid had been continually negative, the blood sulfanilamide level had been maintained around 25 mg. per hundred cubic centimeters and the child had improved remarkably. All meningeal signs had disappeared, but she showed signs of anemia; there were 3,200,000 red blood cells and 167 cells in the spinal fluid, with 40 per cent polymorphonuclears. It was decided to stop the sulfanilamide therapy and do a transfusion (300 cc.). During the ensuing period of convalescence, a number of cultures were made of material from the mastoid, and these showed a total absence of hemolytic streptococci. The evolution was toward an uneventful recovery. Dr. Lyons found that there was no increase in the antibody level at this time.

CASE 6.—First Admission.—L. S., a girl aged 9 years, entered the hospital April 15, 1938, with suppurative otitis media on the right side of two weeks' duration, which had followed spontaneous rupture of the drum. The otitis had been preceded by a cold. Three days before entry the patient had presented dizziness, nausea and vomiting, chills and sweats, and headaches on the right side. Two years previously she had had a discharge from the left ear for three weeks. She was thin and pale and complained of pain in the right ear and of right hemicrania. Examination of the right middle ear showed an anterior-inferior perforation through a thickened drum, an abundant purulent discharge and postaural thickening and tenderness. The left middle ear appeared normal. The nose, throat and eyes were normal. Roentgenograms, interpreted by Dr. A. S. MacMillan, showed "decalcification with destruction in the right mastoid." The temperature was 100.8 F., the pulse rate 120, the respiratory rate 27 and the white blood cell count 14,000, with 96 per cent polymorphonuclears.

April 16 a simple mastoidectomy was performed on the right side. Destruction was found about the antrum and also in the tip. A perisinus abscess was found; the sinus was widely uncovered. No dura was exposed. The culture showed hemolytic streptococci. The day after operation sulfanilamide therapy was started; 45 grains was given the first day, 30 grains the second day and 15 grains each day thereafter.

April 18, two days after the operation, the rectal temperature rose to 102 F. The left ear drum became injected and soon began to discharge spontaneously. April 20, four days after the operation, the rectal temperature rose to 105.6 F. There

was no chill. Blood cultures were reported negative. Neurologic examination and examination of the nose, throat and chest gave negative results.

April 21 a roentgenogram was reported by Dr. MacMillan as disclosing "decalcification in the left mastoid." On account of the history of disease in the left ear two years before and the severity of the clinical signs, a simple mastoidectomy on the left and revision of the right mastoid were advised. These operations were done April 21. In the left mastoid destruction was found around the antrum. The rest of the mastoid appeared normal. No dura was exposed. The right mastoid was revised and found filled with granulations. A small area of dura was exposed. The sinus was covered by a pad of healthy granulations in the area previously exposed. The color appeared normal, and the sinus filled well. The temperature curve was irregular, reaching 103 F. during the five days following the operations, and then became flat.

May 8, seventeen days after the operations, both middle ears being dry and both postaural wounds healing, the patient was discharged to the outpatient department. The sulfanilamide therapy was discontinued on discharge.

Second Admission.—The patient was readmitted June 5, twenty-eight days after discharge and cessation of sulfanilamide therapy, with a history of increase of the discharge through the left postaural wound, of vertigo and frontotemporal headache one day before admission and of a chill. The morning of admission she had presented nausea and vomiting and had begun to complain of pain in her left hip. She did not appear particularly ill. Examination of the right ear revealed a dry middle ear and a nearly healed right postaural wound. The left ear showed a purulent discharge from the middle ear and from the postaural wound. The nose and throat were not remarkable. The eyes showed no nystagmus; the fields and fundi were normal. Neurologic examination gave negative results, and lumbar puncture yielded a clear fluid, with an initial pressure of 100 mm., 2 lymphocytes and a normal reaction to the compression test. The temperature was 102.5 F., the pulse rate 116, the respiratory rate 24, the white blood cell count 10,200, with 90 per cent polymorphonuclears, the red blood cell count 4,220,000 and the hemoglobin content 85 per cent. Blood for culture was taken. Roentgenograms disclosed a normal petrous bone and a postoperative mastoid. There were no chills.

June 7 a revision of the left mastoid was done. The sinus appeared thickened in the area previously exposed. June 7, blood cultures showed a growth of hemolytic streptococci. Sulfanilamide was given, 60 grains (3.8 Gm.) the first day, 30 grains the second day, 20 grains the third day and then 15 grains daily. After the operation the temperature became normal and remained so. The blood culture was positive on the day of the operation and negative thereafter. The involvement of the hip rapidly cleared up. The patient's general condition improved rapidly, her only complaint being a fleeting but recurring frontotemporal headache on the right side. Repeated lumbar punctures yielded normal fluid. June 30 the patient was discharged from the hospital and the sulfanilamide therapy was discontinued.

Third Admission.—The patient was readmitted, semicomatose, to the hospital July 6 after what appeared from the family's description to be a generalized convulsion. This was six days after discharge and cessation of the sulfanilamide therapy. The child had complained frequently of frontotemporal headache on the right and had presented nausea and vomiting. There had been no injury to the tongue during the convulsion. She emerged from her semicomatose condition a half hour after admission. The neurologic examination showed a suggestion of rigidity of the neck. Examination of the eyes, nose and throat was unproductive. The right ear showed a completely healed postaural incision and a healed anterior-inferior perforation, and all the landmarks could be made out on the tympanum. Examination of the left ear showed a slight mucopurulent discharge from the lower portion of the postaural incision and from the middle ear through an anterior-inferior perforation. The rectal temperature was 100 F., the pulse rate 130, the respiratory rate 28, the white cell count 21,000,

with 92 per cent polymorphonuclears, the red cell count 3,950,000 and the hemoglobin content 83 per cent (Sahli). Chemical analysis showed protein 22 mg. and sugar 70 mg. The lumbar puncture showed a cloudy fluid with a pressure of 220 and 285 cells, of which 28 per cent were polymorphonuclears, and a positive Tobey-Ayer reaction on the right side. Blood for culture was taken. Dr. Lyons saw the patient in consultation. In view of the previous treatment with sulfanilamide, it was decided to carry the sulfanilamide blood level up to from 20 to 25 mg. per hundred cubic centimeters. Sulfanilamide therapy was started; 150 grains (10 Gm.) in divided doses every four hours was given the first day and 180 grains (11 Gm.) the second day.

July 7, the day after admission, the laboratory reported that the cultures of the blood and the spinal fluid showed beta-hemolytic streptococci. The rectal temperature had not gone over 101 F. There was no chill. The patient was perfectly rational and presented a slightly stiff neck and a suggestion of Kernig's sign. Lumbar puncture yielded a slightly hemorrhagic fluid with a pressure of 350 and 202 cells, 64 per cent of which were polymorphonuclears. Compression tests could not be performed, the patient not cooperating. The eyegrounds were normal.

July 8, on account of the presence of a discharging postaural wound, the left mastoid was reentered and the lateral sinus, which appeared normal, was uncovered from the knee to the bulb. The dura was widely decompressed and appeared normal. A cisternal puncture was then done and yielded hemorrhagic spinal fluid like that obtained by spinal puncture. It was then decided to explore the right mastoid if the headache on the right side persisted. A bacterial antibody test by Dr. Lyons showed 56 per cent of the cells phagocytizing. It was decided that, in view of the relatively high antibody level, the sulfanilamide level could be brought down to 15 mg. per hundred cubic centimeters.

During the next two days the child complained constantly of temporofrontal headache on the right. She had a slightly stiff neck, Kernig's sign was present and there was marked drowsiness. Exploration of the right mastoid was postponed one day. These signs disappeared on the third day. Neurologic signs of localization could be found, and the blood cultures were negative, the spinal fluid cell count was rapidly dropping and all cultures of the spinal fluid were negative. Clinically the patient was improving rapidly.

July 18 all the signs and symptoms had disappeared and the spinal fluid cell count, which had been dropping steadily, reached 11, with 3 polymorphonuclears. All cultures of the blood and spinal fluid were negative. The white blood cell count reached 10,200, with 68 per cent polymorphonuclears. Two transfusions of 250 cc. of blood had been given July 9 and 11. The mastoid wound, which had been left wide open, was filling in with healthy granulations, and the middle ear was dry. The sulfanilamide blood level had been maintained at about 15 mg. per hundred cubic centimeters, during the entire period the highest level reached being 24 mg. and the lowest 10.8 mg. per hundred cubic centimeters.

August 2, in view of sustained improvement and a complete absence of the previous signs, and after three successive cultures of material taken from the mastoid wound showed an absence of hemolytic streptococci, sulfanilamide therapy was stopped. A transfusion of 500 cc. of blood was given; after the cessation of the sulfanilamide therapy and the transfusion, an improvement in the patient's general condition was noted.

August 13 a plastic closure of the left postaural wound was performed, and the patient left the hospital August 20.

CASE 7.—*First Admission.*—R. S., a boy aged 8 years, was admitted to the hospital May 20, 1938, with suppurative otitis media of five weeks' duration on the right side and three weeks' duration on the left side. Three weeks before admission he had had measles, after which the left ear began to discharge. For three days he had a swelling in the left zygomatic area. There were no chills and no headaches. Examination of the right ear showed thick pus draining abundantly through a high anterior perforation. There were no postaural signs. The

left ear showed a thick red drum with a posterior-inferior perforation, thick pus draining, the canal wall sagging, postaural swelling extending into the zygoma and tenderness.

Roentgenograms revealed destruction of the right mastoid and in the left mastoid cells in the tip and over the knee of the sinus. Pus was present. The rectal temperature was 101.2 F., the pulse rate 112, the respiratory rate 28 and the white blood cell count 18,200, with 90 per cent polymorphonuclears. Lumbar puncture disclosed a pressure of 125 mm., clear fluid and no cells. Compression tests suggested a block on the right side.

May 21 a simple mastoidectomy was performed on each side. The right mastoid was completely broken down and contained pus; no dura or sinus was exposed. In the left mastoid the cells were completely broken down and pus was present under pressure. A small arca of sinus was exposed and appeared normal. A large zygomatic development was cleaned out and a subperiosteal abscess drained through an anterior counter incision. No dura was exposed. Cultures showed hemolytic streptococci.

May 23, the day after the operation, the rectal temperature rose to 105 F. There was no chill, and a blood culture was reported negative. There were no neurologic signs. Signs of consolidation were found in the left side of the chest and were confirmed by x-ray examination. May 24 sulfanilamide therapy was begun, 60 grains being given the first day, 40 grains (2.6 Gm.) the second day, 30 grains the third day and 15 grains the following days. May 28 evidence of fluid in the pleural cavity was found. A thoracentesis yielded clear fluid. Cultures of the sputum showed hemolytic streptococci. A culture of the fluid removed by thoracentesis showed no growth.

May 31, the eighth day after operation, the temperature, which had been between 104 and 105 F., came down to 97.5 F. A crisis occurred. The pleural fluid resorbed slowly during the following days. Both mastoids healed rapidly, the middle ears stopped running and June 30 the patient was discharged to the outpatient department. Sulfanilamide therapy was stopped.

Second Admission.—July 9, nine days after discharge and interruption of the sulfanilamide therapy, the patient was readmitted with a history that the day before swelling had appeared in the left zygomatic area. No other symptoms were noted. On admission the right middle ear was dry and there was a small amount of mucopus discharging from the mastoid wound; the left ear showed a discharge of mucopus through a posterior-inferior perforation and through the postaural wound. A diffuse tender swelling was noted in the left zygomatic area. The rectal temperature was 101.5 F., the pulse rate 108, the respiratory rate 24 and the white blood cell count 23,000, with 94 per cent polymorphonuclears. Roentgenograms revealed an abscess of cells in both mastoids. It was decided to employ conservative treatment with hot poultices before revising the left mastoid. The rectal temperature reached 103 F. Two days after admission the temperature was down to 100.5 F. and the zygomatic swelling had disappeared.

July 13, four days after admission, the patient had acute tonsillitis and a culture of material from the throat showed hemolytic streptococci. The temperature rose to 104 F. Sulfanilamide was not administered, but irrigation of the throat was started. Three days later (July 16) the pharynx had cleared up and the temperature was normal.

July 17, seventeen days after cessation of sulfanilamide therapy, the temperature rose suddenly to 102 F. at 3 a. m. The patient began to complain of frontal headache and showed slight stiffness of the neck but no Kernig or Babinski sign. While being examined he presented projectile vomiting. Lumbar puncture showed a pressure of 210 mm. and cloudy fluid with 2,500 cells, 95 per cent of which were polymorphonuclears.

On account of the recent zygomatic involvement on the left side, it was decided to operate immediately on that side. The tegmen was found to be soft and the dura to be injected, granular and covered with a fibrinous exudate. On further decompression the injection of the dura was found to be limited to an area of approximately 2 by 3 cm. All the soft bone of the tegmen was removed. The sinus was widely exposed and appeared normal.

Sulfanilamide therapy was immediately started, 150 grains being given the first twenty-four hours and a blood level of 7.2 mg. being reached within seventeen hours. The next morning the neck was definitely stiff and there was a Kernig sign but no Babinski sign. No other neurologic signs could be found. The spinal fluid taken for culture the previous day was reported in twenty-four hours to show hemolytic streptococci. Blood culture was negative. The level of sulfanilamide in the blood reached 15 mg. per hundred cubic centimeters the second day, was maintained at this point and then was gradually elevated, reaching 24.4 mg. the eleventh day. Improvement was continuous, the meningeal signs disappeared within three days and cultures of the spinal fluid were all negative after the first one.

Sulfanilamide therapy was stopped fourteen days after it was begun, three successive cultures having shown an absence of hemolytic streptococci in the wound. August 13 a plastic closure of the wound was performed, and August 30 the patient was discharged to the outpatient department.

TABLE 3.—Summary of Cases in Which Late Meningitis Developed After Mastoidectomy and Sulfanilamide Therapy

Case	Age, Yr.	Sulfanilamide		Date of Occurrence of Meningitis*	Antibody	Effective Days	Sulfanilamide in Blood, Mg. per 100 Cc.
		Days	Dose, Gm. Daily				
5	6	15	1	20 days	Very low	10	25
6	9	23	1	27 days	Present	27	15
7	8	7	1	17 days	Not determined	14	25

* Days elapsing between the cessation of sulfanilamide therapy and the onset of meningitis.

These cases of late meningitis are summarized in table 3. All three patients recovered, but it required large doses of sulfanilamide to sterilize effectively the spinal fluid. The blood antibody in case 5 was low both before and after therapy. It is felt that in case 6 septic thrombophlebitis on the right side was probably "masked" by the negative blood cultures obtained when the patient was receiving small doses of sulfanilamide. On the basis of this and similar evidence it seems likely that sulfanilamide therapy may produce negative blood cultures when the patient has a persistent septic endophlebitis capable of exacerbation on withdrawal of the drug.

COMMENT

It is believed that this evidence demonstrates that the institution of sulfanilamide therapy creates an obligation to continue it until there is bacteriologic as well as clinical evidence of complete subsidence of infection. Premature cessation of the drug therapy on clinical evidence alone permits exacerbation of the infection in patients whose defensive mechanism is not prepared to deal with residual living streptococci.

Bacteriologic sterility of the inflammatory process is evidenced by:

1. Absence of streptococci and pus cells in smears from the site of infection.

2. Absence of streptococci in cultures made by planting swabs in 10 cc. broth. (It is necessary to dilute the exudate in broth to overcome the bacteriostatic effect of the drug.) Cultures should be repeated from three to five days after discontinuation of sulfanilamide therapy and prior to discharge of the patient. A word of caution is given as to the interpretation of blood cultures from patients receiving sulfanilamide. Negative cultures may be reported because the blood is planted in a quantity of culture broth inadequate to dilute the

drug beyond the bacteriostatic concentration present in the blood. This "masking" effect may lead to oversight of a complicating endophlebitis that merits jugular ligation or further surgical drainage.

The clinical experience with sulfanilamide at the Massachusetts Eye and Ear Infirmary has led to the belief that sulfanilamide should be reserved for the treatment of spreading or life-endangering infections and that it should not be used as an adjunct to the usual measures for the treatment of infections of minor severity. There are three reasons for this belief: 1. Premature initiation of drug therapy has made complete clinical evaluation of the patient difficult, and progress of the infection to a complicating endophlebitis has been obscured during treatment. 2. There has been recurrence and further spread of the infection after omission of sulfanilamide in patients who had clinically appeared to be healed, so that it is clear that the use of sulfanilamide necessitates fairly extensive laboratory studies to confirm the clinical impression of subsidence of the infection. 3. The amount of sulfanilamide required to sterilize a focus of infection is so large that the danger of toxic manifestations necessitates the hospitalization of all patients receiving the drug.

SUMMARY

1. Inadequate sulfanilamide therapy has been followed by recurrence of otitic infections with beta-hemolytic streptococci.

2. The laboratory studies which are required for the effective use of sulfanilamide necessitate hospitalization of patients under treatment.

3. Sulfanilamide therapy should be reserved for the treatment of spreading or life-endangering streptococcal infections.

121 East Sixtieth Street.

ABSTRACT OF DISCUSSION

DR. BERNARD J. McMAHON, St. Louis: Dr. Converse has mentioned the importance of chemotherapy or serotherapy when the response to sulfanilamide therapy is inadequate, since without the timely mobilization of the phagocytic cells at the area of infection chemotherapy will be unavailing. Sulfanilamide can exert a bacteriostatic effect for only a certain length of time before toxic signs may develop; consequently, the adjunct treatments should be resorted to within the first forty-eight to seventy-two hours. Sulfanilamide should not be administered unless the patient is kept in bed and under the careful and constant observation of his physician. It is the duty of the physician to warn patients of the dangers of ill advised and uncontrolled administration of this drug, and one may hopefully look forward to the enactment of legislation in every state prohibiting the sale of sulfanilamide, sulfapyridine and their allied products by the druggist without a physician's prescription.

Lister Was His Own Bacteriologist.—The cause of human disease never has been, and never can be, found purely within the walls of a laboratory; there must be at least some association, direct or indirect, with patients. This association has grown, especially in the case of bacteriology, to be too loose; it is quite necessary to the proper study of many diseases that the association should develop the intimacy which has proved so successful in investigation of tropical disease. Let us remember that Lister was his own bacteriologist. The solution is not usually to be found in what has been termed team work. Can it not be hoped that skilled clinicians will be found in this country who will devote their lives in studying the origin of disease, and who will fit themselves by special and appropriate training for this particular task?—Lewis, Sir Thomas: Research in Medicine and Other Addresses, London, H. K. Lewis & Co., Ltd., 1939.

GENITAL TUBERCULOSIS

ELI A. MILLER, M.D.

DENVER
AND

MISCHA J. LUSTOK, M.D.

SPIVAK, COLO.

In this discussion we are primarily interested in genital tuberculosis in the male. Much progress has been made in this field in the past few years.

INCIDENCE

The incidence of genital tuberculosis will of course vary with different authors, depending on the type of material under observation. The average figures given in the literature vary between 2 and 8 per cent of male tuberculous patients. At the Sanatorium of the Jewish Consumptives' Relief Society in the eleven year period of observation (January 1928 to January 1939) sixty-one of a total of 1,316 male patients admitted had genital tuberculosis, an incidence of 4.7 per cent.

Clinical evidence of tuberculosis in the male genital tract occurs during the age of greatest sexual activity, and the vast majority of patients range from 20 to 40 years. In our series the mean age of incidence of genital

TABLE 1.—Incidence of Genital Tuberculosis

Period of Observation—January 1928 to January 1939	
Total number of patients admitted to the sanatorium	1,890
Total number of male patients	1,316, or 69.9%
Total number of male patients with genital, renal or combined urogenital tuberculosis	84, or 6.4%
Total number of male patients with genital tuberculosis	61, or 4.7%
Of the 61 patients with genital tuberculosis	
15, or 24.5%, had associated proved renal tuberculosis	
46, or 75.4%, had no definite evidence of renal tuberculosis	
Of the 61 patients with genital tuberculosis	
58, or 95.0%, had associated far advanced pulmonary tuberculosis	
2, or 3.2%, had associated moderately advanced pulmonary tuberculosis	
1, or 1.6%, had no associated pulmonary tuberculosis	
Of the 61 patients with genital tuberculosis	
53, or 86.8%, had sputum containing tubercle bacilli	
8, or 13.1%, had normal sputum	

tuberculosis was 30 years. That genital tuberculosis may occur at any age is evident by the report of the Greenbergers and Alexander,¹ whose series showed patients ranging from 2 to 67 years of age. It is well recognized that the younger the patient the more virulent the infection. In a greater sense this is also true of pulmonary tuberculosis.

PATHOGENESIS

Genital tuberculosis is accepted as secondary to some other tuberculous focus in the body, the focus being most commonly found in the respiratory system, whether clinically apparent or not. It is agreed that the infection may reach the genital tract directly by way of the blood stream from a focus elsewhere in the body, by way of the lymphatics and, secondarily, by continuity of tissue.

Young's studies bring out the fact that whereas the epididymis attracts more attention and gives more pronounced symptoms, especially at the onset of the disease, the seminal vesicles and the prostate are in fact

the primary seat of the genital tuberculous infection.² The prostate and seminal vesicles are not only the primary focus from which the epididymis is involved but also the focus from which the bladder and the kidneys in many cases are affected. Menville,³ Braasch,⁴ Bumpus and Thompson⁵ and the Greenbergers and Alexander¹ have expressed the same opinion. Barney, Watson and Elliott⁶ and Caulk⁷ have said, on the contrary, that the epididymis is the seat of primary genital involvement and that the infection is hematogenous in origin.

In the opinion of Campbell,⁸ genital tuberculosis without renal involvement is a hematogenous infection and starts in the epididymis, whereas with renal tuberculosis the infection reaches the genital tract by way of the urinary passages. The tuberculous urine bathing the prostatic portion of the urethra causes the prostate and seminal vesicles to be involved first. He further stressed the role as a focus of the avascular vas deferens, which keeps the vesicles and prostate constantly reinfected, most probably by extension along the lumen or possibly by extension along the lymphatics.

Moore⁹ presented histologic and correlative evidence that the bacilli in most cases reach the prostate and seminal vesicles through the blood stream and that the prostatic lesion is secondary to other urogenital lesions in less than 20 per cent of the cases.

There are then two general theories concerning the pathogenesis of tuberculosis of the male genital tract:

1. That the prostate and seminal vesicles are involved primarily in the genital system and that the disease may remain localized or spread as descending genital or ascending renal tuberculosis.
2. That the prostate and seminal vesicles are involved secondarily from other urogenital organs by dissemination through the lumens or walls of hollow viscera connecting them, ascending genital or descending renal tuberculosis.

It must be borne in mind that the presence of genital tuberculosis does not preclude the presence of renal tuberculosis, and vice versa. While the two conditions do commonly occur together, each will occur independently of the other in sufficient frequency to warrant individual consideration. In the eleven year period of our observation there were twenty-three cases of renal tuberculosis without genital involvement, fifteen cases of combined renal and genital tuberculosis and forty-six cases of genital tuberculosis without renal involvement. Furthermore, the presence of urine showing tubercle bacilli on direct smear or guinea pig inoculation is not pathognomonic of renal tuberculosis, since the urine can be infected from a genital tuberculous lesion alone by means of the discharge into the posterior portion of the urethra. In our series of sixty-one cases there were forty-six cases of genital tuberculosis without proved renal involvement, in thirteen of which the urine contained tubercle bacilli.

It is our belief, based on our clinicopathologic observations, that the disease most frequently starts in the vesicles and prostate but may occasionally start in the epididymis. The mode of infection is primarily hematogenous.

Genital tuberculosis is principally a disease of the structures apart from the testis, the latter remaining intact in the presence of extensive long standing dis-

TABLE 2.—*Relation of Onset of Genital Tuberculosis to That of Pulmonary Tuberculosis in Sixty-One Cases*

Mean age of onset of pulmonary tuberculosis about 27 years
Mean age of onset of genital tuberculosis about 30 years

Of the 61 cases of genital tuberculosis

Genital tuberculosis developed in 47 from 1 to 20 years after pulmonary tuberculosis, but in the majority within 3 to 10 years

In 5 cases genital tuberculosis developed from 1 to 5 years before the onset of pulmonary tuberculosis

In 7 the patient was unaware of his genital tuberculosis, which was diagnosed on admission

In 1 the onset was not known

In 1 pulmonary tuberculosis has not yet developed

case of the epididymis, only becoming involved by contiguity very late. In the large majority of cases, both epididymides eventually show clinical evidence of tuberculosis, though there may be a long interval before this is observed.

DIAGNOSIS

The difficulty in accurate diagnosis of the scrotal and prostatic masses has been emphasized frequently, yet the chief underlying cause is incomplete investigation.

The only method available for the examination of the prostate and seminal vesicles is palpation with the finger in the rectum. In the early stages of the disease no change may be demonstrable by this means of examination, but in the vast majority of cases definite signs are present. Irregular, firm but not stony hard nodules in the prostate recognized by means of touch indicate extensive involvement of this organ. Likewise when the seminal vesicles are felt as pencil-like bands, extending in an upward and outward direction

TABLE 3.—*Classification of Genital Tuberculosis*

1. Catarrhal

A lesion clinically characterized by predominant evidence of tissue breakdown; this lesion is soft or even fluctuant and the masses are as a rule comparatively large; there is no evidence of sinus formation, although it may seem imminent; the presence of a hydrocele (allergic effusion) will place a lesion in this class

2. Ulcerative

A lesion clinically characterized by the presence of draining scrotal sinuses, irrespective of the state of the scrotal mass

3. Fibroid

A lesion clinically characterized by predominant evidence of fibrosis or calcification; there are no soft or fluctuant masses and no hydrocele or sinus formation; a lesion with a hard fibrotic scrotal mass and with old, healed, not active sinuses may be included in this class

Occurrence of the Types of Genital Tuberculosis

In the 61 cases there were

8 cases of catarrhal genital tuberculosis, in 8 of which there was no evidence of renal tuberculosis

21 cases of ulcerative genital tuberculosis, in 5 of which there was proved renal tuberculosis and in 16 of which there was no evidence of renal tuberculosis

32 cases of fibroid genital tuberculosis, in 10 of which there was proved renal tuberculosis and in 22 of which there was no evidence of renal tuberculosis

from the upper margin of the prostate, extensive involvement of these organs is indicated.

Examination of the external genitalia is best done with the patient in a standing position facing the surgeon. Observations are made of alterations in the normal rugose appearance of the skin of the scrotum, the shape of the testicles and their relative position in respect to each other. Changes in the scrotal skin are

sometimes a valuable guide, as shown by a smoothing out of the rugae and a wasting of the cellular tissue immediately beneath the dermis. Adhesion of the skin to the epididymis is a well known sign, as is also a sinus discharging creamy pus. A comparison of the mobility of the two testicles is sometimes helpful. A normal organ can be moved freely within its covering, particularly in the upward and downward direction. This movement is often restricted when tuberculosis of the genital organs is present. In the early stages a soft or even fluctuant mass at the site of the epididymis and involving it is present in a large percentage of cases. If untreated, it will result in ulceration and formation of a chronic sinus discharging pus or it will become a hard, fibrotic or calcific mass. Late in the disease the epididymis may entirely lose its identity or, if it can be palpated, will be craggy and nodular. The vas becomes thickened and has beadlike prominences.

CLASSIFICATION

Genital tuberculosis has the same macroscopic and microscopic characteristics as tuberculosis elsewhere in the body, and its clinical-pathologic behavior simulates

TABLE 4.—*Other Extrapulmonary Tuberculous Lesions Associated with Genital Tuberculosis (Exclusive of Renal Tuberculosis)*

Of the 61 cases of genital tuberculosis

In 27, or 44.2%, the condition was not associated with other extrapulmonary tuberculous lesions

In 34, or 55.7%, the condition was associated with other extrapulmonary tuberculous lesions

In 26 there was only one extrapulmonary tuberculous lesion

14, tuberculosis of the larynx

5, tuberculosis of the osseous system

3, tuberculous ischio-rectal fistula

2, tuberculous chronic otitis media

2, ileocecal tuberculosis

In 8 there was more than one extrapulmonary tuberculous lesion

3, tuberculosis of larynx and ileocecum

2, tuberculosis of larynx and osseous system

1, tuberculosis of ileocecum and osseous system

1, tuberculosis of larynx and ischio-rectum

1, tuberculosis of skin and osseous system

Total

20 cases, associated tuberculosis of the larynx

9 cases, associated tuberculosis of the osseous system

4 cases, associated tuberculous ischio-rectal fistula

6 cases, associated ileocecal tuberculosis

2 cases, associated tuberculous otitis media

1 case, associated tuberculosis of the skin

that of pulmonary tuberculosis. The phthisiologist has long been classifying pulmonary tuberculous lesions into various types, depending on the predominant pathologic process, and has based the necessity for a sanatorium regimen, the indications for collapse therapy and the prognosis on the clinical-pathologic classification. Similar types of tuberculous lesions exist in the case of genital involvement and show a parallel response to treatment. A discussion on genital tuberculosis which does not take into consideration the clinical-pathologic type of tuberculosis but merely includes all cases under a blanket heading of genital tuberculosis is not justified.

We have divided the genital tuberculosis in our cases into three main classes, as shown in table 3.

As is true of pulmonary tuberculosis, these types represent various stages in the tuberculous pathologic process, the end result being fibrosis.

OTHER EXTRAPULMONARY LESIONS ASSOCIATED WITH GENITAL TUBERCULOSIS

If the mode of infection in genital tuberculosis is hematogenous, as stated, it would be logical to suppose that other parts of the human anatomy would become seats of tuberculous infection at the same time as the

genitalia, while the blood stream was laden with tuberculous bacillary emboli. This is indeed the fact. In our series thirty-four patients, or 55.7 per cent, had tuberculous lesions outside the lungs and kidneys.

The prevalence of other extrapulmonary tuberculous lesions associated with genital tuberculosis strengthens the theory of the hematogenous route of infection.

PROGNOSIS

The life expectancy of the patient with far advanced cavernous pulmonary tuberculosis who has received no form of active therapy was studied by Schwatt and Rest¹⁰ at our institution. The 267 patients had a racial and sociologic background similar to that in our series. They found that only 38 per cent of the untreated patients with this type of tuberculosis were alive at the end of the three to ten year period. In our

Fig. 1.—Life expectancy of patients with genital tuberculosis (sixty-one patients). Note that this is not parallel to that of patients with far advanced pulmonary tuberculosis, as it is generally accepted to be.

series 95 per cent of the patients had far advanced pulmonary tuberculosis and 27.8 per cent received successful pulmonary collapse therapy. Our patients therefore were in much better condition than those of Schwatt and Rest, who did not receive collapse therapy, and should have shown a much longer life span if the prognosis of genital tuberculosis cases depends entirely on the prognosis of the associated pulmonary lesion. On the contrary, at the end of a one to eleven year period of observation only 34.4 per cent of our patients were alive. It becomes obvious then that the presence of genital tuberculosis adds considerably to the gravity of the general disease and shortens the life expectancy.

The cause of death was as a rule attributed to tuberculosis in general, although three patients died of tuberculous meningitis and three of uremia with a basis of renal tuberculosis.

10. Schwatt H., and Rest, A.: Prognosis of the Cavity Bearer. *Am. Rev. Tuberc.* 37: 65-70 (Jan.) 1938.

During the period of observation, of the patients with the catarrhal type four, or 50 per cent, died; of those with the ulcerative type fifteen, or 71 per cent, died, and of those with the fibroid type twenty-one, or 65 per cent, died.

TREATMENT

There are two distinct schools of thought with reference to therapy. The surgical treatment recommended varies from a careful resection of the infected focus¹¹ to the complete removal of the seminal tract.¹² The immediate mortality rate of radical surgical management, the persistent draining sinuses that are frequent sequelae of such intervention and the false rationale of removing a single focus and leaving the primarily infected prostate have placed this form of therapy in general disrepute among phthisiologists and urologists versed in the management of tuberculosis.¹³

The beneficial effect of ultraviolet therapy in extrapulmonary tuberculosis has been well known for many years. Myl¹⁴ reported most favorably on cases of treatment with solar exposure at the Fitzsimons General Hospital in Denver. Other authors have reported successful results in the treatment of genital tuberculosis with ultraviolet therapy¹⁵ and a sanatorium regimen.¹⁶ It is logical to choose a form of therapy which will lend itself to sharp localization to the desired areas, that is the prostate, the seminal vesicles and the epididymis, thus producing the maximum local effect without doing any general harm. Irradiation of the epididymis alone has been common practice among the men who advocate this form of physical therapy for genital tuberculosis. It is our belief that if radiation was given with equal intensity to the prostate and seminal vesicles, the most frequent primary seat of tuberculous infection in the genital tract, the result would be more certain and more rapid and reactivation would be less likely to occur.

GENERAL CONSIDERATIONS OF ULTRAVIOLET RADIATION

The crythemagenic efficiency of a lamp as tested on untanned skin is of importance in determining the individual sensitivity of the patient to the ray in order to avoid serious burns, but it is not a measure of the therapeutic action of the source of ultraviolet ray.¹⁷ The popular use of the presence and extent of erythema as an index of therapeutic efficiency of a lamp is erroneously founded. Certain sources of radiation capable of producing erythema in a comparatively short time have little therapeutic effectiveness, and vice versa. Other criteria for determining the therapeutic value of

TABLE 5.—Report of Cases of Genital Tuberculosis Treated by Means of Ultraviolet Radiation of the Wavelength 2,537 Angstroms

Case No.	Age, Yr.	Classification and Duration of Pulmonary Tuberculosis	Clinical Status	Complications	Duration of Genital Tuberculosis	Type of Genital Tuberculosis	Anatomic Involvement	Renal Status	Previous Treatment of Genital Tuberculosis	Results	Period of Treatment with Ultraviolet Rays, 2,537 Angstroms	Results
1	37	Far advanced; 3 yr.; thoracoplasty	Ambulant and clinically well; working	None	2 yr.	Catarrhal	Right epididymis, prostate	No tuberculous; results of cystoscopic examination negative	None	14 mo.	Absorption of mass; no sinus formation; small residual in right epididymis and prostate
2	25	Far advanced; 10 yr.; pneumothorax discontinued	Ambulant and clinically well; working	None	1 yr. 2 mo	Catarrhal	Left epididymis, prostate	No tuberculous; normal	None	10 mo.	Absorption of mass; no sinus formation; moderate residual in left epididymis and prostate
3	38	Moderately advanced; 1 yr.	Ambulant and clinically well; working outside of sanatorium	None	Diagnosed on admission	Catarrhal	Left epididymis, prostate	No tuberculous; normal	None	3 mo.	Reduction in size of mass; no sinus formation; moderate residual in left epididymis and prostate
4	32	Far advanced; 8 yr.	Bed patient	Ischiorectal abscess	4 mo.	Catarrhal	Left epididymis, prostate, left seminal vesicle	Urine contained tubercle bacilli; no renal lesion proved	None	5 mo.	Reduction and hardening of mass; no sinus formation; residual in prostate and seminal vesicle
5	28	Far advanced; 4 yr.	Bed patient	Tuberculosis of larynx	1 yr. 11 mo.	Ulcerative	Both epididymides, prostate, seminal vesicle; bilateral scrotal sinuses	Albuminuria; urine did not contain tubercle bacilli; no renal tuberculous	Ultraviolet irradiation with water-cooled machine, 3 mo.	No effect	39 mo.	Closure of all scrotal sinuses; marked reduction in size of scrotal mass and prostate
6	39	Far advanced; 6 yr.; phrenic avulsion on left	Ambulant and clinically well	None	2 yr. 1 mo.	Ulcerative	Both epididymides, prostate, seminal vesicle; bilateral scrotal sinuses	No tuberculous; normal	Irregular and infrequent ultraviolet radiation	No effect	18 mo.	Closure of all scrotal sinuses; marked reduction in size of scrotal mass and prostate
7	24	Far advanced; 10 yr.; thoracoplasty	Ambulant and clinically well; not in sanatorium	None	3 yr. 9 mo.	Ulcerative	Right epididymis, prostate; bilateral scrotal sinuses	Albuminuria and occasional pus; urine contained tubercle bacilli	Ultraviolet irradiation with water-cooled and water-cooled machine; 2 yr.	Slight reduction in mass; sinuses not affected	12 mo.	Closure of two sinuses and reduction of third to minimum; marked reduction in size of scrotal mass and prostate
8	35	Far advanced; 19 yr.	Ambulant and clinically well; not in sanatorium	None	2 yr.	Ulcerative	Right epididymis, prostate; scrotal sinuses on right	Nephrectomy on right for tuberculous; 8 yr. before	Natural heliotherapy	No effect	1 mo.	Slight reduction in size of scrotal mass; marked reduction of drainage from sinuses
9	51	Far advanced; 9 yr.	Bed patient	Ossous tuberculosis; tuberculosis of skin	8 yr.	Ulcerative	Both (right residual) epididymides, prostate, seminal vesicle; multiple scrotal sinuses	Bilateral renal tuberculous; early nonprotein nitrogen retention	Infrared and ultraviolet irradiation 3 yr. before; removal of scrotal mass on right 7 yr. before	Closure of sinuses until 3 yr. before; increase in size of scrotal mass	4 mo.	Marked reduction in drainage from sinuses and one sinus closed; no change in size of mass
10	35	No pulmonary tuberculosis	Ambulant and clinically well	None	2 yr. 3 mo.	Fibroid	Left epididymis, prostate	Nephrectomy on left and epididymectomy and orchiectomy on right 1½ yr. before; tuberculous	None	12 mo.	Reduction of scrotal mass almost to normal; no change in prostate
11	33	Far advanced; 7 yr.; phrenic avulsion on left; pneumothorax on right	Ambulant and clinically well	None	1 yr. 9 mo.	Fibroid	Left epididymis and seminal vesicle, prostate	No tuberculous; results of cystoscopic examination negative	None	16 mo.	Slight reduction in size of scrotal mass; no other change
12	52	Far advanced; 25 yr.; thoracoplasty	Bed patient	Chronic tuberculous otitis media	4 yr.	Fibroid	Left epididymis, prostate	Renal tuberculous on left proved by cystoscopic examination	Ultraviolet irradiation 3 yr. before	Increase in fibrosis and retraction of both cords	11 mo.	No remarkable change
13	45	Far advanced; 17 yr.	Ambulant and clinically well; not in sanatorium	Chronic tuberculous otitis media	3 mo.	Fibroid	Prostate only	Urine contained tubercle bacilli; no evidence of renal tuberculous	None	5 mo.	No remarkable change
14	44	Far advanced; 1½ yr.; pneumothorax	Ambulant and clinically well	None	3 yr.	Fibroid	Right epididymis and seminal vesicle, prostate	No tuberculous; results of cystoscopic examination negative	None	5 mo.	No remarkable change
15	43	Far advanced; 1 yr.	Bed patient	Tuberculosis of larynx	Diagnosed on admission	Fibroid	Right epididymis and seminal vesicle, prostate	No evidence of renal tuberculous	None	5 mo.	No remarkable change

a commercial lamp must then be employed. The rational means of evaluation of the therapeutic efficiency of the commercial sources of the ultraviolet ray are based on the quantitative and qualitative characteristics of the spectrum emission. After careful study we have chosen the so-called cold quartz lamp as the source of ultraviolet ray in the treatment of genital tuberculosis.

Fig. 2.—Treatment of the epididymis with topical applicator of the so-called cold quartz ultraviolet lamp. Note that the burner is at contact to the scrotal skin and that the epididymis is held against the burner by the operator's hand.

This has essentially a low vapor pressure, a low amperage (0.015 amperes), a high potential (5,000 volts, open circuit) and a glow discharge similar to the well known Geissler tube. The power consumed is small and consequently there is no great rise in the temperature of the burner.¹⁸ The advantages of this commercial source of ultraviolet rays lie in its effective administration and its characteristic spectrum emission. The burner is "cold," exceeding room temperature only after about an hour of continuous operation, and thus the actual source of radiation can be placed directly on and in contact with the target. This fact increases the total quantitative output of the so-called generator manyfold as compared with other commercial sources

Fig. 3.—Treatment of prostate and seminal vesicles with the rectal applicator of the so-called cold quartz ultraviolet lamp. Note that the applicator is covered to within 6 cm. of its tip to prevent exposure to the anal sphincter and that the applicator is tipped so that the exposed end lies directly on the prostate and seminal vesicles.

of ultraviolet ray. The latter, because of the heat generated at the burner, must be kept some distance from the target (the air cooled machines at least 36 inches and the water cooled machines from 3 to 6 inches, depending on the type of quartz conduit used). Since ultraviolet rays are essentially light rays, they are dis-

seminated inversely to the square of the distance. When the factor of air absorption is added to the loss by dissemination, it becomes obvious that the machine which will permit application of the source in contact with the target will deliver a greater quantity of ultraviolet rays than a machine whose burner must be kept at a distance from the area under irradiation.

The mechanical ease of manipulation and the immediate maximum output (there is no "warming up" period characteristic of other commercial sources) make the so-called cold quartz apparatus very desirable. The various applicators which emit radiation with equal intensity at all points and angles and which are available for topical, orificial, rectal and anal irradiation at contact to the tissues involved add further to the clinical efficiency of administration. While the quantitative appreciation of ultraviolet irradiation has been commonplace since its inception, the qualitative studies of the ultraviolet spectrum and the characteristics of its component wavelengths have been of recent origin in the clinical literature. Most of the commercial sources of ultraviolet rays produce radiation of mixed wavelengths,

Fig. 4 (case 1).—Result of treatment of genital tuberculosis of the entarial type. Note the complete gross restitution to normal. On palpation a small fibrotic residual could be detected in the epididymis. The prostate was small and fibrotic.

predominantly between 2,537 and 3,130 angstroms,¹⁹ while the so-called cold quartz lamp emits a spectrum whose intensity along a wavelength of 2,537 angstroms is within 95 per cent of its total spectrum emission, to all practical purposes a monochromatic radiation.¹⁹ The biologic effects of monochromatic ultraviolet radiation in the wavelength of 2,537 angstroms have been extensively studied. The bactericidal action (*Bacillus coli*),²⁰ growth restriction of tissue culture,²¹ coagulation of albumin²² and hemolysis²³ have their peak effectiveness with radiation in the region of a 2,537 angstrom wavelength. The peak of the ergosterol activation curve (formation of vitamin D) has been credited by some workers to wavelengths other than 2,537 angstroms,²⁴ and Van Wijk and Reerink have even claimed destruction of vitamin D by radiation of this wavelength. A greater number of workers have,

however, found ultraviolet radiation of the wavelength 2,537 angstroms unusually active in the production of vitamin D, both in vitro by activation of ergosterol and in vivo by cure of rickets in experimental animals.²⁵

MODE OF TREATMENT

In our series we employed the monochromatic ultraviolet radiation of 2,537 angstroms emitted (95 per cent) by the so-called cold quartz lamp as the sole direct therapeutic agent. All irradiation was done with the burner in direct contact with the tissues treated. Treatment was given twice weekly. The initial dose of fifteen seconds exposure was given to each epididymis by scrotal contact and to the prostate and seminal vesicles through the rectum. This was increased by fifteen seconds weekly, until at the end of the first seven weeks of treatment a full two minutes treatment was given

TABLE 6.—Summary of Results in the Treatment of Genital Tuberculosis By Means of Monochromatic Ultraviolet Radiation with a Wavelength of 2,537 Angstroms

1. Fifteen patients with genital tuberculosis were treated with ultraviolet radiation of the wavelength 2,537 angstroms for from 1 to 19 months
2. Four patients with catarrhal genital tuberculosis were thus treated with
 - (a) Prevention of sinus formation in all 4
 - (b) Absorption of the scrotal and prostate masses, with small residuals, in 2
 - (c) Reduction in the size of the masses in the scrotum and prostate in 2
3. Five patients with ulcerative genital tuberculosis were thus treated with
 - (a) Complete closure of all sinuses in 2
 - (b) Closure of some of the sinuses, with reduction in drainage from the remaining sinuses, in 2
 - (c) Marked reduction in drainage from all sinuses in 1
 - (d) Marked reduction in the scrotal and prostate masses in 4
 - (e) No change in the masses in 1
4. Six patients with fibroid genital tuberculosis were thus treated with
 - (a) Reduction in the size of scrotal and prostate masses in 1
 - (b) Slight reduction in the size of the scrotal mass in 1
 - (c) No remarkable change in 4

Conclusions

1. Ultraviolet radiation of wavelength 2,537 angstroms is of greatest value in the treatment of catarrhal and ulcerative genital tuberculosis and of lesser value in the treatment of fibroid genital tuberculosis
2. The most distressing complication of genital tuberculosis, draining sinuses, has been successfully prevented in cases of the catarrhal type in which breakdown of the tissue seemed imminent and successfully eliminated in cases in which it was already present; the patients with incomplete closure of the sinuses can be considered as not yet adequately treated
3. This form of treatment has been less effective, if at all so, in the treatment of fibroid genital tuberculosis; this condition, like fibroid pulmonary tuberculosis, presents the predominant picture of healing by fibrosis and in all probability does not require any treatment

over each area treated. Treatment was continued semi-weekly without interruption for from ten to twelve months, after which there was a two months rest period. Only patients who showed inadequate improvement from the first course were given the second. Total and differential white blood counts were made twice monthly in anticipation of the leukopenia occasionally seen as a result of heavy ultraviolet therapy, but this condition was never seen in our cases.

RESULTS OF TREATMENT OF GENITAL TUBERCULOSIS WITH MONOCHROMATIC ULTRAVIOLET RADIATION OF 2,537 ANGSTROMS

The period of observation in this group of cases was from one half to two years. The majority of the patients had had their genital tuberculosis for two years or longer. With two exceptions the condition was associated with far advanced pulmonary disease. Of the twenty-one patients with genital tuberculosis (in our series of sixty-one) who are alive at the present time,

fifteen received monochromatic ultraviolet radiation of 2,537 angstroms. While the greatest mortality for the entire series with genital tuberculosis was for the first two years of the illness, the majority of these fifteen patients had their disease two years or longer, and none of this group have died. The results appear striking in spite of the brief period of observation.

Fig. 5 (case 5).—Result of treatment of genital tuberculosis of the ulcerative type. Note the healed scrotal sinuses and the restitution of the normal rugose appearance of the scrotum. Reduction in the size of the scrotal mass was marked, and the epididymis was no longer embedded in the mass and could be individually palpated. The prostate was markedly reduced in size and was firm. The seminal vesicles were barely palpable.

From the social and economic standpoint this form of treatment is also very favorable. Of these patients only five are undergoing absolute bed rest; four are totally ambulant, two are ambulant and working in the sanatorium and four are clinically well and living outside the sanatorium and working. The favorable effect on the progress of the far advanced pulmonary tuber-

Fig. 6 (case 11).—Result of treatment of genital tuberculosis of the fibroid type. Note only slight reduction in the size of the scrotal mass and the absence of other demonstrable change.

culosis in these cases by the arrest of the genital tuberculosis cannot be denied. This form of therapy aptly lends itself to office practice.

In the analysis of the results obtained in the treatment of genital tuberculosis by means of ultraviolet radiation of 2,537 angstroms, the need for the aforementioned classification of genital tuberculosis becomes apparent. In the cases of the catarrhal type the results were the most striking.

The ulcerative type of genital tuberculosis showed the next best results.

25. Goldblatt, H.: Prevention and Cure of Rickets in Rats and Anti-rachitic Activation of Ergosterol by Cold Quartz Mercury Lamp, *Proc. Soc. Exper. Biol. & Med.* 30: 380-383 (Dec.) 1932. Windaus, A.: Einige weitere Erfahrungen über das bestrahlte Ergosterin, *Nachr. Ges. Wiss. Göttingen* 1: 36-37, 1930. Action of Monochromatic Actinic Radiation, editorial, *Arch. Phys. Therapy* 14: 107-109 (Feb.) 1933.

The third type of genital tuberculosis, that is the fibroid type, showed the least apparent change under treatment.

SUMMARY

1. A statistical analysis of cases of genital tuberculosis observed in an eleven year period of 1,316 male admissions to the Sanatorium of the Jewish Consumptives' Relief Society was presented.

2. A classification for genital tuberculosis was proposed, based on the clinicopathologic interpretation of the lesions and their response to treatment.

3. Ultraviolet ray therapy was advocated in preference to surgical treatment of genital tuberculosis, and encouraging results in the treatment of the catarrhal and ulcerative types was reported.

4. The consideration of the quantitative and qualitative spectrum output of a commercial source of ultraviolet ray based on the individual biophysical characteristics was stressed.

ABSTRACT OF DISCUSSION

DR. HOMER C. HAMER, Indianapolis: The authors present a summary of the results of treatment of fifteen cases of genital tuberculosis by ultraviolet radiation. Since no mention is made as to what treatment was given in the remaining forty-six cases of the series, it may be inferred that orthodox methods were employed. If so, a comparison of results would be interesting and it is to be hoped that a later report may give data in the other forty-six cases. In the five cases with sinuses, complete closure had occurred in two. There was improvement in two cases and no change in one case. Of the six cases of fibroid tuberculosis, two were improved while four showed no change. The results obtained in the series by palliative treatment may be as good as could be expected in a group of cases of far advanced tuberculosis, in some of which possibly even conservative surgery was contraindicated. Yet one may question whether the prognosis was greatly improved. Spontaneous arrest of the disease sometimes occurs, which tendency would be enhanced by sanatorium treatment, but there is little justification for nonoperative treatment in operable cases. Epididymectomy or castration is advocated by the majority of surgeons. Good results are reported by Young and others who advocate radical excision of the seminal vesicle, prostate, vas and epididymis, together with the testicle if it is involved. The mortality and operative results are about the same whichever site of primary focus is adhered to and whether conservative or radical surgery is performed. From 53 to 80 per cent of clinical cures are obtained by epididymectomy. Local morbidity following this operation is slight. Sinus formation following high excision of the vas is uncommon. The observation of most observers is that following epididymectomy the disease in the seminal vesicles and prostate not only ceases but retrogresses to a point of clinical cure. It is highly improbable that the operation, conservative or radical, removes all the tuberculous tissue. Arrest of the disease following operation depends on the ability of the body defense to control the remaining infection. Palliative treatment preceding and following operation in the more advanced cases should enhance the success of surgery. From the results obtained by Drs. Miller and Lustok, it is fair to predict that ultraviolet radiation may find a place as an adjuvant to the surgical treatment of genital tuberculosis.

DR. M. J. LUSTOK, Spivak, Colo.: I would stress the point that we are dealing with persons who came to Denver primarily for the treatment of pulmonary tuberculosis. These patients are different in their behavior from the group which presents genital tuberculosis alone without clinical pulmonary involvement. We are convinced that genital tuberculosis adds to the gravity of the pulmonary disease and that the prognosis of the individual is not dependent on the progress of the pulmonary disease alone. The successful management of the genital tuberculosis is as important as the management of the pulmonary tuberculosis in the treatment of an individual so afflicted.

THE BRONCHOSCOPIST AND THE
THORACIC SURGERY TEAM

M. F. ARBUCKLE, M.D.

AND

A. C. STUTSMAN, M.D.

ST. LOUIS

After several years' experience as members of a thoracic surgery team, we have become convinced of the importance and value of teamwork in the diagnosis and treatment of numerous types of pulmonary disorders. Although there is not unanimous accord with the following statement, we feel that thoracic surgery has already become a highly specialized division of general surgery and that special training for this type of surgery is required.

The improved methods of diagnosis and treatment now available make it possible to obtain results in the treatment of certain varieties of pulmonary disorder which are far better than have been achieved heretofore. Treatment of some of these conditions may be carried out by so-called medical care alone, this may be combined with bronchoscopic treatment, or the two methods may be combined with surgical intervention. As an adjunct to medical treatment we find that bronchoscopic treatment is much more efficacious in certain conditions, notably lung abscess, than we had reason to believe only a short time ago. In some pulmonary disorders it is true that relief is to be found only through surgical intervention, an outstanding example being endobronchial cancer. Either lobectomy or total pneumonectomy is at the present time the only hope for curing this disease, which until five years ago had a mortality rate of 100 per cent. As is well known, in April 1933 the first successful total pneumonectomy as a means of treating cancer of the lung was carried out by Dr. Ewart Graham.¹ The patient is alive and carrying on with his profession as an obstetrician without a sign of recurrence. The microscopic diagnosis of cancer in this case was established by study of a biopsy specimen obtained by us through the bronchoscope. Dr. Graham informed us on Dec. 23, 1938, that in the last seven cases of total pneumonectomy for cancer of the lung there had been only one operative death. Before the planning of treatment for this or any other obscure pulmonary condition, such as abscess, unexplained endobronchial stenosis or unexplained variation in tuberculosis, a diagnosis is essential, and an absolute diagnosis is particularly important in the case of tumor of the lung. It is obvious that the only method of making a definite diagnosis of a tumor is by study of a biopsy specimen, which can be obtained only with the bronchoscope.

As a result of our experience and from conversation with men from other centers we are convinced that the most successful operations on the chest are accomplished as a result of teamwork by a group of men, each a specialist in his own field, who collaborate in each case in establishing the diagnosis and in outlining and administering treatment. Such a group properly consists of an internist who is especially interested in thoracic disorders, a thoracic surgeon who is a specialist in this

field by reason of actual and thorough training, a bronchoscopist similarly qualified, an expert radiologist, a pathologist and a bacteriologist. It would seem that special training on the part of the pathologist in the field of tumors of the tracheobronchial tree increases his usefulness as a member of a thoracic surgery team. Tumors of all kinds are difficult of classification in some instances when a decision is wanted as to malignancy, but apparently tumors of the respiratory tract possess this quality in a more marked degree than do ordinary tumors. The difference of opinion and the occasional inability to establish an opinion are based on sound reasoning. One possible explanation is the fact, often unrecognized, that a tumor may be made up of more than one variety of cells. We have in our laboratory a specimen of an endobronchial cancer in which at least four grades (Broders²) of cells have been found. Many pathologists, radiologists and cancerologists feel that the degree of radiosensitivity of a given tumor may be prophesied within limits by the microscopic appearance of its cellular make-up. It is well known that tumors frequently do not live up to this prognostication. The presence of several varieties of

duction of the oil will be far more satisfactory if the operating room is equipped with adequate x-ray apparatus and if the tube is focused before the oil is put in so that the exposure may be made before the position of the oil is disturbed by coughing. Interpretation of bronchograms presupposes an accurate knowledge of the topographic anatomy of the tracheobronchial tree. The bronchoscopist, furthermore, is a more valuable member of the team if he is also a trained otolaryngologist, because of the fact that many pulmonary disorders are secondary to those of the upper respiratory tract.

Bronchoscopic examination entails much more than the mere introduction of the bronchoscope, but it is very important that the instrument be passed into the trachea without injury to the lips, teeth, tongue, gums, pharynx or larynx and without mental hazard to the patient. Careful inspection will reveal notable departures from the normal, if they are present, in the visible portion of the tracheobronchial tree, namely the larynx, trachea and the larger bronchi and even the opening of the bronchus to the various lobes. With instruments especially designed for this purpose, we are at times

Fig. 1 (case 1).—A plain anteroposterior film showed a tumor in the right lung near the border of the heart. The patient was a woman aged 65.

Fig. 2 (case 1).—A localizing anteroposterior bronchogram showed blocking of the bronchus to the middle lobe of the right lung.

Fig. 3 (case 1).—A localizing lateral bronchogram showed blocking of the bronchus to the middle lobe of the right lung with atelectasis. In view of this information the bronchoscope was introduced directly into the bronchus of the middle lobe after the necessary dilation had been carried out. The tumor was then visualized and a biopsy specimen recovered. A diagnosis of benign adenoma was made by microscopic examination, and roentgen treatment was recommended.

cells within the tumor, unrecognized because of failure to study the entire tumor, may be the basis for this disappointment.

Most pulmonary disorders may be discovered and recognized by means of x-ray and physical study, but they may be much more accurately localized and their exact nature may be more definitely established by visual examination through the bronchoscope and the study of specimens obtained during the examination. The bronchoscopist will carry on more satisfactorily when and if he is competent to make a physical examination of the chest and to interpret films for himself. Bronchograms may be made as a rule by the house officer working with the team, according to the simple method suggested by Singer,³ whereby the oil is introduced directly into the larynx with the patient in front of the fluoroscope. In an occasional case this is impossible, and then the oil is introduced through the bronchoscope and a film made while the patient is on the table. Bronchograms made by bronchoscopic intro-

enabled to see lesions well up within a branch bronchus. Some of the changes to be found are alterations in the position, shape and size of the tubes; the presence of blood or pus in the tubes; changes in the appearance of the mucosa, including its color, and the presence of ulcer, scar tissue, tumor masses and, of course, foreign body. Thus, for example, changes in the position, shape and size of the tubes may be caused by pressure on their walls by a tumor mass which is located outside the tubes. Similar changes may be caused by the pressure accompanying pneumothorax, by a mass of enlarged glands or by adhesions. Inflammatory changes in the mucosa itself will encroach on the lumen but usually do not change the actual shape of the tube or its position. As is true with inflammation elsewhere in the body, there is usually redness as well as swelling. When one finds blood or pus or both one must localize the lesion by tracing these secretions to their source. This is best accomplished by the use of suction and repeated inspection at the same sitting. We are presup-

posing, of course, careful physical and x-ray examinations, including the making of bronchograms, before bronchoscopic examination is carried out.

When scar tissue is found as a basis for endobronchial stenosis the stricture must be dilated, secretions carefully collected for bacteriologic study and evidence of recent inflammatory reaction noted. In such cases tuberculosis and syphilis must be ruled out. Indeed it should be routine practice to secure a specimen of secretions whenever possible, for laboratory study, including, when indicated, guinea pig injections. The rather unusual disorder, such as actinomycosis or other fungous disease, will be detected in this way, while otherwise the diagnosis might be missed. We have observed an occasional case in which tubercle bacilli in the pulmonary secretions were demonstrated in a specimen obtained by bronchoscopic suction when the patient did not have sufficient sputum to cough up a specimen in the amount required for examination. We have one patient who had localized tuberculosis in the upper lobe of the left lung with blocking of one of the

At all times the bronchoscopist must be prepared to deal with hemorrhage. This is of comparatively rare occurrence, but when it does happen it is a most serious matter and requires immediate and exact management if one is to avoid asphyxiation as soon as the blood clots, which it does promptly, or possible exsanguination or postoperative complications such as pneumonia.

Avoidance of mental hazard to the patient is an important feature always, but particularly when the patient is suspected of having tumor or other disorder for the relief of which surgical intervention will be required later. We find that we have much less difficulty in arranging for such treatment if the patient has been shielded at the time of the bronchoscopic examination, and also we are certain that if the patient is asleep the bronchoscopic examination can be carried out in a much more satisfactory manner. For these reasons we have employed avertin with amylene hydrate for all our bronchoscopic examinations for several years, and we see no reason to alter this practice.

An occasional case is observed in which by bronchographic examination one may establish that the obstructive

Fig. 4 (case 1).—This view and others showed a decrease in the size of the tumor and in the area of atelectasis.

Fig. 5 (case 2).—Pudding denotes the area of granulation tissue which was treated by actual cautery. The patient was a woman aged 36.

Fig. 6 (case 3).—A filling defect in the trachea extends from the level of the second rib posteriorly down into the lower lobe of the right lung, where extensive bronchiectasis is seen. The tuberculous granulations in the trachea and at the opening of the right bronchus were removed with the biting forceps and the actual cautery. The patient was a woman aged 37.

branches of the bronchus of this lobe by granulation tissue and subsequent atelectasis. The differential diagnosis between cancer and tuberculosis was made by studying secretions obtained with a curved suction tube which at the same time traumatized the granulation tissue so that it bled. The application of suction and the bleeding were followed promptly by ventilation and drainage of the atelectatic lung. This patient was treated locally and by general medical care three years ago. She was away from her employment for the period of about a year but has been back at work for two years.

When a tumor mass is found, its position must be definitely established by actual measurement and a biopsy specimen taken. Some time ago one of us (M. F. A.) described a method of measuring the distance between the proximal portion of a tumor and the carina. This method is highly important to the thoracic surgeon when he is contemplating surgical removal of a lobe or a lung. Tumors in the vicinity of the carina have a tendency to grow by direct extension across the dividing line and obstruct the bronchus of the other side. Temporary relief of obstructive symptoms may be afforded by removal of the tumor with the forceps and the actual cautery.

tive lesion is within one of the smaller bronchi at sufficient depth to place it beyond the range of ordinary bronchoscopic visibility, or it may be in a bronchus which is placed at such an angle as to prevent introduction of the bronchoscope (figs. 1, 2, 3 and 4, case 1). In the former instance it occasionally is possible to dilate the bronchus sufficiently to introduce the bronchoscope and permit visualization and recovery of a biopsy specimen under visual guidance; or it may be necessary to take the biopsy specimen without actually seeing the tumor by simply introducing the forceps to the point indicated on the bronchogram. This method is obviously unsatisfactory for numerous reasons and of course is employed only of necessity. The results are conclusive only when positive. We have had one case of carcinoma of the upper lobe of the right lung in which the tumor was around the corner to such an extent that it was impossible to see it or get the forceps up to it. By inducing artificial pneumothorax with the patient supine and then placing him in a semiprone position, it was first demonstrated that there were no adhesions between the lung and the parietal pleura in the apical region.

Later the bronchoscope was introduced, and again the air was allowed to float up, as does the bubble in the carpenter's level, under fluoroscopic guidance with the bronchoscope in position and with the pneumothorax needle in position. More air was then introduced, and the tumor was forced down under fluoroscopic visualization until the lumen of the bronchus containing the tumor was on an axis parallel with that of the bronchoscope. The bronchoscope was then pushed into the bronchus containing the tumor, the tumor visualized and a specimen taken. The results of biopsy in this instance were negative for cancer, but transthoracic exploration confirmed the inferential diagnosis of endobronchial carcinoma. The method of taking biopsy specimens from endobronchial tumors, or from other tumors, for that matter, is a subject worthy of considerable discussion, but for lack of space we will merely say that more than once we have had negative results from a biopsy when we felt certain that the correct diagnosis was cancer. In some instances it was discovered that the reason for the failure to demonstrate cancer cells was that the specimen was not cut deeply enough through

lene hydrate and local anesthesia. The lesions have entirely disappeared and the sputum has become free from tubercle bacilli. The patient had no untoward constitutional reaction from any of the several applications of the cautery.

The second patient (fig. 6, case 3) was a young married woman who had had pulmonary tuberculosis for some time and who finally came to us because of continued difficulty with breathing. She had a high degree of tracheal stenosis with stridor and cyanosis. The tracheal obstruction was readily demonstrable with films made after injection of iodized oil. Inspection revealed the fact that her trachea was filled, except for a narrow slit, with granulation tissue from a point about midway between the cricoid cartilage and the bifurcation down to and into the right main bronchus. She also had a severe bronchiectasis in the lower lobe of the right lung, which was the affected side. We have been able with the biopsy forceps and the cautery to relieve her respiratory difficulty and with the suction to relieve the signs of absorption which she was getting from the bronchiectasis. We realize of course that this

Fig. 7 (case 4).—A filling defect in the lower lobe of the left lung behind the heart and close to the midline shows the location of a bronchiectatic lesion at this point. This observation was confirmed by endobronchial inspection and by examination of the specimen after lobectomy. The patient was a boy aged 10 years.

Fig. 8 (case 5).—A filling defect in the right main bronchus denotes the point of lodgment of a foreign body, removed through the bronchoscope. This body probably caused the bronchiectasis. The nature of the bronchial obstruction could not be established except by direct inspection. A diagnosis of tumor had been made and was not untenable. The patient was a woman aged 42.

Fig. 9 (case 6).—A post-tonsillectomy lung abscess of three years' duration in a woman aged 38. The plain roentgenogram showed a shadow in the lower lobe of the right lung which at first glance appeared to be in the upper lobe (a mistake which is commonly made). After detailed study for localization the abscess was demonstrated to be in the apical division of the lower lobe.

the surrounding layer of fibrous tissue to include the cancer cells. This is exactly what happened in this case. In other cases the specimen was taken from the immediate vicinity of the tumor rather than from the tumor itself.

For years we have been on the lookout for localized lesions of the tracheobronchial tree in tuberculous patients, but not until comparatively recently was it our fortune to see one that could be identified as such, and then came three in rapid succession in Dr. Graham's service.

The first patient (fig. 5, case 2) had had a successful pneumothorax but the sputum had continued to show tubercle bacilli, which the internist and the thoracic surgeon were at a loss to explain. Bronchoscopic examination revealed the fact that she had an ulcer on the surface of the carina on the side of the affected lung and an ulcer and granuloma in the bronchus to the upper lobe on the affected side. These were treated by repeated applications of the actual cautery through the bronchoscope with the patient under avertin with amy-

is almost a hopeless situation, but we are trying to free the trachea of its involvement in the hope that we may later be able to recommend a lobectomy or a pneumonectomy for the tuberculosis and bronchiectasis.

The third patient was a physician's wife who also had long standing tuberculosis on the right side and pneumothorax. When it was decided to let the lung expand by releasing the pneumothorax, the lung failed to expand. When she came to Barnes Hospital she had severe respiratory difficulty with marked stridor and cyanosis. Bronchoscopic examination revealed a high degree of obstruction at the lower end of the trachea caused by external pressure and displacement into the lumen of the wall on the left side. There was also present a mass of granulation tissue which completely obstructed the right main bronchus at the carina. It was necessary to apply some force in passing a 9 mm. bronchoscope through the obstruction in order to displace outward the tracheal wall. Then the granulomas were visualized and touched with the actual cautery. With the first treatment the patient had immediate relief

from dyspnea and cyanosis, and she has continued to improve with subsequent treatments. The lung has expanded somewhat.

Bronchiectasis is a disease of frequent occurrence and may be found at any age. It occasionally is complicated by hemorrhage due to ulceration into a sizable blood vessel. The hemorrhage may be severe enough to necessitate lobectomy as an emergency measure. Such a condition was found in a 10 year old boy (fig. 7, case 4), who had had pneumonia six months prior to admission to the St. Louis Children's Hospital in the service of Dr. Evarts Graham in the summer of 1938. When admitted he was having pulmonary hemorrhage several times a day, and he had required numerous blood transfusions before coming to St. Louis. On his arrival it was found that his red cells numbered 3,200,000 and his white cells 8,600 and that his hemoglobin content was 70 per cent. He continued to spit up blood in the amount of 150 to 250 cc. once or twice a day. A plain film showed evidence of disorder in the lower lobe of the left lung behind the heart. A bronchogram made immediately by the direct method showed a filling defect in the same region. On bronchoscopic examination we found the tracheobronchial tree more

is well known, was done years ago, but this method of treatment was more or less abandoned because of the terrific mortality rate. With the methods of today a well trained thoracic surgeon has no hesitation in recommending a lobectomy in a suitable case. Our own operative mortality is now less than 5 per cent.⁴

Abscess of the lung is an important and serious disease of rather frequent occurrence, in the diagnosis and treatment of which the bronchoscopist may play a most important part. First of all, abscess of the lung in adults not infrequently is caused by a foreign body or by failure of resolution of a disease such as pneumonia, and not infrequently it is the result of bronchial obstruction by an endobronchial cancer. We as laryngologists are especially interested in the condition, since in a high percentage of cases it follows tonsillectomy. Inspection of the tracheobronchial tree in search of the cause as well as for the purpose of localization is important in diagnosis and treatment. We have found that a fairly good percentage of the patients will make complete recovery by bronchoscopic treatment combined with medical care, which consists chiefly of rest in bed and postural drainage. This is contrary to the opinion which we held a few years ago. Bronchoscopic treat-

Fig. 10 (case 6).—Iodized oil was injected into the abscess cavity after removal of granulation tissue from the fistulous opening and evacuation of inspissated pus.

Fig. 11 (case 6).—The important lateral view demonstrates beyond doubt that the abscess is in the apical division of the lower lobe.

Fig. 12 (case 6).—Remarkable clearing in keeping with the patient's general condition, which, as far as one can make out from her statement, is normal.

or less blood stained throughout. With the application of suction it was found that the source of this blood was in the mesial division of the bronchus to the lower lobe of the left lung. A diagnosis of bronchiectasis with ulcer localized to the lower lobe of the left lung was made and immediate lobectomy recommended. This was done on the following morning, two transfusions having been required in the meantime. The diagnosis was confirmed at operation, and the accompanying illustration (fig. 7) shows the involvement of the lobe itself. The boy made an uncomplicated recovery and has had no hemorrhage since the operation.

Every patient with bronchiectasis should have at least one bronchoscopic examination because of the possible presence of an unsuspected foreign body (fig. 8, case 5) or bronchial stenosis caused by scar tissue or granulation tissue. If a foreign body is found, removal will promote drainage and ventilation and help to improve the patient's general condition. Bronchoscopic therapy alone will not cure bronchiectasis, but it does make life more livable for the patient and improves his chances for recovery if lobectomy is to be done later. We are convinced that once bronchiectasis is well established the only hope of cure is surgical removal of the affected portion of the lung. Lobectomy for bronchiectasis, as

ment of abscess of the lung as we apply it consists in the removal of granulation tissue if present from around the fistula leading into the abscess by the use of the sponge curet, the biting forceps or sometimes the cautery, dilation of the fistula, the use of special suction tubes and the introduction of remedies which we think help to reduce the virulence of the infection. These consist of 1 per cent guaiacol in oil of sweet almond and iodized poppyseed oil in spite of discussion pro and con. It is our feeling that iodized poppyseed oil introduced into these cavities, even for bronchographic examination, often has a very salutary effect on the infection present. Coupled with such treatment we always carry on with postural drainage. Careful study of properly made localizing films before bronchoscopic treatment facilitates entering the cavity. The study of laminagrams helps us in deciding whether or not the abscess cavity is single or multiple.

We have had made several special flexible metallic suction tubes with which we have been able to enter and drain abscess cavities which we could not otherwise reach through the bronchoscope. We have one patient who had had an abscess for three years following

4. Graham, E. A.; Singer, J. J., and Ballon, Harry C.: *Surgical Diseases of the Chest*, Philadelphia, Lea & Febiger, 1935.

tonsillectomy. According to her own statement, the bronchoscope had been used twenty-seven times before she came into Dr. Graham's service (figs. 9, 10 11 and 12, case 6). At the first sitting we found granulation tissue obstructing the fistula leading into the abscess. After removal of this granulation tissue the stench was so terrific that the assistants and nurses in the room were sickened by it. With one of the special flexible tubes we were able to enter the cavity, which was very large and which was filled with inspissated pus. In this case, as in another case which we are here-with reporting (figs. 13, 14 and 15, case 7), there was momentarily free bleeding apparently from granulation tissue. According to our experience such bleeding apparently diminishes the granulation tissue and improves drainage. The chronic unilocular abscess with exuberant granulation tissue which bleeds when suction or sponging is done and which has a very foul odor offers a good prognosis for recovery with bronchoscopic treatment alone. The bleeding is usually readily controllable by the application of epinephrine and cocaine on a sponge. Sometimes even this is not required.

When one considers the difference in the hazard between bronchoscopic treatment of lung abscess and

considerably increased. One reason for the increase in the number of positive diagnoses almost certainly is the fact that more accurate diagnostic methods are being employed. There are authorities who think that there is an actual increase, and while this may be true we are inclined to think that the increase is more apparent than real. Until well within our time the diagnosis of endobronchial cancer was made by inference, until the patient came to the autopsy table, or until the cancer filled the pleural cavity, or until occasionally a piece was broken off and coughed up or until metastasis to a superficial location permitted biopsy. Now in a large percentage of cases it is possible actually to secure a biopsy specimen from endobronchial tumors, and, as we remarked earlier in this paper, actually to localize the tumor. Tuttle and Womack⁵ from a study of our cases found that as a rule there is a much greater life expectancy for the patient whose endobronchial cancer is in the larger tubes than for the one whose cancer arises in the smaller tubes. It is also possible at times for the bronchoscopist to obtain by palpation with the end of the bronchoscope some idea as to the presence or absence of fixation of the hilar portion of the lung by pleural adhesions or by pressure from a peribronchial tumor.

Fig. 13 (case 7).—Involvement of the lung early in the course of the disease in a man aged 21 referred to us by Dr. John R. De Velling, Rosiclare, Ill., Aug. 25, 1938. Plate shows area of infiltration of the right hilar region, which was again the apical division of the lower lobe. There is no cavitation at this time.

Fig. 14 (case 7).—Plate made four months later for comparison shows increased distribution of infiltration with cavitation in the center of the shadow. Aug. 25, 1938, with bronchoscopic visualization granulation tissue was removed from the fistula leading to the abscess in the apical division of the lower lobe of the right lung and a large quantity of inspissated and extremely foul-smelling pus was evacuated with the special suction tip. Although the patient had had a septic temperature for about a year, his temperature promptly fell to normal, and on the following day, to use his own expression, he had "an appetite like a horse." After three bronchoscopic treatments he returned to his home, and a communication from him dated Nov. 3, 1938, stated that he was entirely well.

Fig. 15 (case 7).—The improvement in the appearance of the chest, visible even at an early date.

external drainage through the chest wall, one realizes how important is the fact that a respectable percentage of patients will get well with this comparatively simple method of treatment. We have been looking over our case records in an effort to discover if possible some method of telling beforehand which patients will and which will not get well with bronchoscopic treatment. To date our only means of answering the question is to institute treatment.

It is recognized of course that a large percentage of all patients with lung abscess recover spontaneously, some without any medical care and many with so little medical care that it amounts to the same thing, while others will recover with rest and postural drainage. But there remain a group who do not recover with this method of treatment, and it is with these that we as bronchoscopists are concerned.

The diagnosis of cancer of the lung is being made much more frequently than it was only a very few years ago, so much more frequently in fact that the incidence in comparison with that of all types of cancer has been

When operations on the lung through the chest wall are to be carried out, we find that for several reasons it is important for the bronchoscopist to be on hand in the operating room and ready to work. The type of anesthesia which is best when the chest wall is opened is endotracheal anesthesia administered by an endotracheal tube connected with apparatus for accurate control of the intrapulmonary pressure. The anesthetist occasionally has difficulty in introducing the endotracheal tube, and the bronchoscopist can help with this. In all types of lung suppuration it has been demonstrated by numerous other workers as well as by ourselves that bronchoscopic suction immediately before and after operation almost surely prevents not only respiratory difficulty during the operation but also the development of postoperative pneumonia.

By the prompt introduction of the bronchoscope and the application of suction, we have been able on several occasions to save the life of a patient who, because of complete tracheal obstruction by pus and blood, had stopped breathing on the table. In each instance after

5. Tuttle, W. M., and Womack, N. A.: Bronchogenic Carcinoma: Classification in Relation to Treatment and Prognosis, *J. Thoracic Surg.* 4: 125-146 (Dec.) 1934.

the trachea had been cleared the patient breathed again, the operation on the lung was completed and the patient is now alive and well. One interesting example is that of a small child with a lung abscess possibly caused by a foreign body. Her condition was so precarious that a preliminary introduction of the bronchoscope was postponed because we felt that immediate drainage of the lung abscess was her most urgent need. After the incision had been made, pleural adhesions had been found, an abscess had been located with a needle and the surgeon, Dr. Brian Blades, had begun to apply the actual cautery to uncap the abscess, the child suddenly quit breathing. She was said to have died of an embolus. Since one of us (M. F. A.) was standing by the head of the table and the bronchoscope was ready for use, immediate inspection of the trachea was undertaken. This showed that its lower end was entirely filled with a blood clot, which came away rapidly in one piece with the suction. With cleaning up of the pus which filled the bronchus and with artificial respiration the child resumed breathing and the operation on the abscess was finished. We had a letter from her mother at Christmas 1938 reporting that she was in perfect health.

Another patient with bronchiectasis, an adolescent who had had preoperative bronchoscopic suction, became cyanotic and quit breathing in the midst of the operation for lobectomy. This operation was abandoned for the moment while bronchoscopic suction was immediately applied by one of us (A. C. S.), who was on hand and ready to work. As soon as the airway was cleared the patient began to breathe, the operation on the lung was completed and the patient made an uneventful recovery.

CONCLUSIONS

Because of improved diagnostic and therapeutic methods, the outlook for persons suffering from a rather wide variety of pulmonary disorders has improved tremendously during the past decade. Of importance in the application of these methods of study and treatment is the realization that this is a special field in which, in order to obtain the best results, the work must be carried out by a group each member of which has been thoroughly trained for his particular job. In our service some of the members of this group find it necessary to have their own individual teams in order to carry on more satisfactorily with their phase of the work.

The epoch making developments in thoracic surgery of the past five or ten years have depended not only on improved surgical technic, anesthesia and postoperative as well as preoperative care, all of which are of first importance, but also on better x-ray and pathologic studies. Probably the greatest single step forward has been early and actual diagnosis by direct inspection of the lesion.

The presence of pulmonary disorder of almost any type may be demonstrated by the usual methods of study, namely physical and x-ray, but unfortunately such studies do not reveal in many cases the exact nature of the disease nor do they demonstrate its endobronchial distribution. These usually may be established by direct endobronchial inspection and by the study of specimens obtained during the course of this inspection.

The same approach is extremely valuable in the treatment of certain varieties of pulmonary disorder, prominent among which are lung abscess and localized tuberculous lesions. The percentage of cures obtained

by bronchoscopic treatment in cases of lung abscess demonstrates the necessity for keeping in mind this method when outlining treatment in such cases. It is of course the accepted method for removal of a foreign body and is the only approach for applying direct treatment to localized tuberculous lesions.

In establishing the cause and location of unexplained pulmonary bleeding, direct inspection (bronchoscopic) has been found most helpful. We have had no unfavorable reaction as a result of the necessary manipulations, and it is our feeling that the propitious time for such examination is while bleeding is active.

Clinical Notes, Suggestions and New Instruments

PYOCYANEUS MENINGITIS

REVIEW OF THE LITERATURE AND REPORT OF AN ORIGINAL CASE

NATHAN SLUTSKY, M.D., AND PAUL MATLIN, M.D., BROOKLYN

We are taking this opportunity of reviewing the literature and presenting a case report of a comparatively frequent saprophyte which on occasion attains moderate virulence and invades the blood stream and nervous system with fatal sequelae.

The general surgeon, while not often troubled by the invasion of *Bacillus pyocyaneus*, encounters it frequently enough to recognize the greenish discoloration over a heretofore healthy granulating surface and may even anticipate it by the characteristic odor suggestive of wet musty hay arising from the dressings. A few applications of boric acid rapidly eradicate the invasion and hence cause no undue concern.

The genito-urinary surgeon meets this organism with more frequency, for the urine appears to be an excellent culture medium. Weiss¹ claims an incidence of 25 per cent following pyelotomy.

Scott² in 1929, while investigating the rigors attendant on instrumentation of the genito-urinary tract, took blood cultures on patients suffering chills and fever above 102 F. Over a period of two years he was able to obtain eighty-two positive cultures, recovering *Bacillus pyocyaneus* three times. This bacteremia was transitory with no sequelae. Hyman and Edelman³ in 1932, repeating this procedure, obtained sixty-three positive cultures and one case of pyocyaneus bacteremia following cystoscopy in a case of renal neoplasm. Barrington and Wright⁴ report twelve positive cultures in a series of eighty-eight cases, with one case of *Bacillus pyocyaneus*. Powers,⁵ in a series of thirty cases, recovered this organism from the blood on one occasion. Ewell⁶ reports a case of pyocyaneus bacteremia following pyelonephritis and prostatic abscess with subsequent death. Fish and his associates⁷ report a case of acute bacterial endocarditis in a man aged 71 after repeated catheterization and suprapubic prostatectomy. He also mentions four similar cases from the German literature.

In 1936 Florence Evans⁸ reviewed the literature on meningitis due to *Bacillus pyocyaneus* and reported a total of forty-two cases, including three of her own. This series included six cases in which there were meningeal symptoms, but no organisms could be recovered from the spinal canal. There were fourteen cases due to direct trauma (spinal tap, injury and the like), four cases of otitic origin and eighteen cases of pyocyaneus meningitis following systemic infection. Of these

eighteen cases fifteen terminated fatally, a mortality of 83 per cent. Since then, Shrewsbury⁹ has reported a case following spinal tap with recovery after repeated drainage. Roberts and Belsey¹⁰ report a case of tuberculous empyema with secondary invasion by *Bacillus pyocyaneus*. Surgical drainage was instituted and on this there followed a meningitis from which the pyocyaneus could be recovered. There was recovery after symptomatic treatment.

REPORT OF CASE

B. B., a woman aged 49, white, admitted to the Beth Moses Hospital Jan. 8, 1937, complained chiefly of pain in the right lumbar region and right upper quadrant for the past three years. The pain was colicky and radiated to both shoulders and downward toward the symphysis. The patient had repeated attacks of this nature and noticed frank blood in the urine on each occasion, accompanied by dysuria. There were no chills or fever. The past personal and family histories were irrelevant.

The patient was examined with a cystoscope and x-rays by one of us prior to admission to the hospital. A large calculus occupying the pelvis and lower calix of the right kidney was visualized. The urine obtained from this side by ureteral catheterization revealed many leukocytes in clumps. Kidney function (by the indigo carmine test) was normal on both sides.

On admission the patient was acutely ill. The only gross abnormalities were spasm in the right upper quadrant and the presence of the Murphy sign on the right side. The blood pressure was 130 mm. of mercury systolic and 80 diastolic. The temperature, pulse and respiratory rates were normal. There were 7,200 white blood cells with 65 per cent polymorphonuclear leukocytes. The urine was cloudy and acid, had a specific gravity of 1.015 and contained no albumin or sugar. There were many erythrocytes and leukocytes present, the latter in clumps.

On January 9 a pyelolithotomy was performed under cyclopropane anesthesia. The stone was removed from the pelvis and two small catheters were inserted into the opening. The following day the temperature rose to 104.2 F., the pulse to 104 per minute and the respiratory rate to 26 per minute. January 11 the temperature was 104.8 F. and the pulse 96. With this discrepancy between pulse and temperature, meningitis was of course suspected. The sensorium was clear but there was evidence of some nuchal rigidity. Inspection of the wound showed a slight greenish discoloration at the drainage tubes with a definite odor of musty hay. *Bacillus pyocyaneus* was obtained on culture. On the third day after operation there was no improvement. The temperature was 104.6 F. and the pulse 90. Blood culture taken revealed *Bacillus pyocyaneus* in the broth; there was no growth on the plates. The urine showed 2 plus albumin with an occasional white cell. The patient's condition remained essentially the same until the sixth day, when a herpetic eruption of the buttocks became evident. On the seventh day the patient became irrational and incontinent and there was moderate distention. Nuchal rigidity was marked and Kernig's sign was present. The patient was given a transfusion. A spinal tap yielded 12 cc. of a light green cloudy fluid under increased tension. There were 4,300 mononuclear cells present and the culture revealed *Bacillus pyocyaneus* in pure growth. January 18, eight days after the operation, there was evidence of a right hemiplegia, speech defect, ankle clonus on the right side and the already noted nuchal rigidity and Kernig sign. The temperature was 102.5 F., the pulse 112 and the respiratory rate 32. Another spinal tap was performed; 10 cc. of a green cloudy fluid under increased pressure was withdrawn. The same organisms were recovered. The patient suffered an attack of pulmonary edema with marked dyspnea. Fifty cc. of 50 per cent dextrose was given intravenously with marked beneficial effect. Bacteriophage was obtained and a course of intravenous therapy instituted. At 4:20 a. m., after 50 cc. of the bacteriophage had been given in graduated increasing doses, the patient suffered a severe chill lasting eight minutes (the desired reaction). The temperature was 104 F., the pulse 120 and the respiratory rate 52.

Another spinal tap was performed, and after withdrawal of 15 cc. of green cloudy fluid 2 cc. of bacteriophage in 8 cc. of saline solution was injected. The patient died on the tenth day after the operation with a complete right hemiplegia present at the time of death.

SUMMARY

In the original case here presented *Bacillus pyocyaneus* was obtained from the wound following a pyelolithotomy for calculus; bacteremia ensued and this organism was recovered from the blood stream; meningitis followed and the same organism was again recovered. From the clinical picture one might justifiably conclude that a solitary cortical abscess had developed with a complete right hemiplegia and motor aphasia as focalizing signs.

PILONIDAL SINUSES IN IDENTICAL TWINS

SAMUEL L. GOLDBERG, M.D., AND ERNEST D. BLOOMENTHAL, M.D.
CHICAGO

Search of the literature reveals only one instance of the occurrence of pilonidal cysts and sinuses in identical twins.¹ The following report of such an occurrence is interesting also because of the appearance of the symptoms at approximately the same time in the two twins:

I. K. and J. K., identical twins, aged 23, in December 1935, within a period of a few days, each noticed a symptom free lump at the end of the spine. One year later, again within a

Pilonidal sinuses removed from identical twins.

few days, both lumps began to drain very slightly. The drainage was serous and in one patient remained so. The other patient had a mild inflammatory reaction in March 1937 with some soreness for several days.

Examination revealed in each case two small openings in the midline over the coccyx into which probes could be inserted about 2 cm. and from which there escaped a small amount of serous drainage.

Both cysts were removed May 3, 1937. They were rather small but typical. The ensuing cavities were closed primarily. One healed by primary union; the other, which previously had been inflamed, drained some serum for a few days but was completely healed within three weeks.

The significance of the occurrence of this developmental defect in identical twins is a question. Whether it is purely coincidental or whether the "anlage" for the defective development is present in the ovum before it splits to form twins, we do not know.

duced. Serum may be given in the presence of purulent complications; then it is impossible to neutralize the antigen present and the collections of purulent material keep pneumococci inaccessible to the antibodies so that the pneumococci continue to multiply. Surgical evacuation is then required in addition. Serum therapy and other specific therapy fail when the pneumococcal infection places an insupportable load on an already weakened mechanism, so that the breaking point is reached and death occurs, as with degeneration of heart, liver or kidney. The exudate which collects in response to the pneumococcus may exert fatal pressure, as in meningitis. Finally, death may be due to reduction of functioning pulmonary tissue, to dehydration or azotemia from loss of chlorides, to other infections and to a number of other circumstances.

Antibody can be measured. The amount of antibody required for neutralization of a given amount of antigen or soluble carbohydrate is measurable, so that the relative strengths of serums can be compared, either outside the body or in an animal. The protection of mice

of early and not too severe involvement in which the organisms are not too virulent. This amount is inferred from the fact that there are, in an average person, approximately 10 liters of blood. If 100,000 units of antibody is diluted in 10,000 cc. of blood, there will be 10 units to each cubic centimeter. Some patients will

Fig. 3.—Type I pneumonia treated with 49 cc. of refined and concentrated antipneumococcus horse serum in three doses in four hours. On the third day, agglutinins which were negative became positive.

against organisms is the accepted value, and for commercial serums its use is required by the National Institute of Health. The titration of serum against a control is shown in figure 2. Antibodies may be measured by the nitrogen united with a known amount of soluble carbohydrate. Antibodies may also be gaged by the amount of capsule swelling they cause under standard conditions. Serums should be clinically tested for reactions under controlled conditions before they are released to practitioners.

The variables present in any given case make an exact estimate of the required dose difficult. The organisms may be few or many, and they may differ in virulence and in capacity to produce soluble carbohydrate. The ability of patients to respond with antibody and the amount of antigen invading organisms liberate are variable. The lung blood barrier produced by local defenses may be ineffectual.

Because it has been observed that there are from 10 to 20 units of antibody in many spontaneously recovering patients, it is probable that 100,000 units in an adult is the amount required to induce a cure in most cases

require much more than this. This is especially true of patients who have bacteremia, who suffer from infection due to pneumococci of type II, III or VII or who have several lobes involved and are seen late in the course of the disease, when much antigen or carbohydrate is present. Because the maximum concentration of antibody is required immediately, it is necessary to give serum intravenously in the shortest possible time consistent with the avoidance of chills and other reactions. Two thirds of the last eighty patients treated with serum at Harlem Hospital received between 100,000 and 300,000 units of antibody, but more was required by the others.

It is well to give a probative dose to determine the reaction of the patient to serum and thus avoid severe reactions, and then to give the remaining serum as quickly as possible. I recommend injection of the serum at intervals of one or two hours into the tube of a running infusion of saline solution and 5 per cent dextrose in progressively increasing doses as illustrated in figure 3. Only with infants is it advisable to give serum intramuscularly. This is an extravagant method,

Fig. 4.—Type IV pneumonia treated with 20 cc. of refined and concentrated rabbit serum in a single dose.

Fig. 5.—The effect of serum therapy on the mortality rate; contrast between hospital and home treatment in the years 1937 and 1938, in the department of public health, Pittsburgh.

because an infant must receive, through the muscle, approximately the same dose as would be adequate for an adult. Figure 4 shows the results of a single dose of refined and concentrated rabbit serum.

At the present time, serums are available for all the types of pneumococci established by Cooper and her co-workers. Serum will have to be prepared for several strains which were not differentiated at the time of her report and for some which cross with the strains segregated and numbered by her. There are undoubtedly types of organisms and possibly conditions of soluble specific substance with which union with antibody is less ready than usual and for which extremely large amount of antibody may be required. The conditions which make for prompt union of antibody and soluble carbohydrate are still not entirely known. With

Serotherapy Versus Chemotherapy

Serotherapy Fortifies the Patient

Advantages	Disadvantages
Neutralizes capsular substance	Is type specific
Sensitizes pneumococci for phagocytosis and lysis	There are resistant types
Reduces virulence	Must be used intravenously
	May cause reactions:
	Anaphylactic
	Thermal
	Serum sickness
	Cost is high

Chemotherapy Depresses the Organisms

Advantages	Disadvantages
Is effective for both pneumococci and streptococci	There are resistant strains
May be used orally	Organisms survive
Is effective for meningitis	There is irregular absorption and concentration
Cost is low	Toxicity may develop
	There may develop symptoms referable to the
	Gastrointestinal tract
	Liver
	Central nervous system
	Skin
	Urinary tract
	There may develop:
	Hemolytic anemia
	Agranulocytosis
	Sulfapyridine sickness

Combination of Drug and Serum

Enhances effectiveness of both agents; supplement drug with serum

patients who have large amounts of soluble carbohydrate already in the blood or in whom the pneumococci have invaded the blood and are in a rapidly multiplying phase, serum will fail unless huge amounts of serum are promptly given; such patients are benefited by the administration of serum. With these patients other methods, such as a chemotherapeutic attack on the pneumococci, by depressing the production of soluble specific substance, may be an important adjuvant.

The clinical results of the administration of serum have been amply demonstrated not only in patients treated promptly in the first few days of the disease but also in those for whom treatment has been delayed. It has been shown that intensity of therapy is a greater factor in securing recovery than the time when serum is administered.

The influence of serum on the course of pneumococcal pneumonia is seen in the regular fall of pulse rate and of temperature as soon as a sufficient amount of anti-serum has been injected. The patient is unpoisoned and frequently is reading the paper on the day after an injection. Bacteremia can no longer be demonstrated, even in cases of heavy invasion. A crisis has been induced. The temperature became normal in twenty-four hours in sixty-eight of the last eighty patients treated with serum. Patients with bacteremia usually required forty-eight hours. But, since a critical fall of

temperature may occur in patients without specific therapy, it is necessary to present proof of benefit. Termination of pneumonia occurs even in cases of early involvement in direct time relation with the administration of the serum instead of at the times expected from observation of the disease unmodified by specific therapy.

With all the variables in patients and in invading organisms, how shall one determine whether lives are saved by using serum? Comparing the results in patients treated with serum and those from whom it is withheld seems an appropriate method. One must, however, compare only those patients in each series who had the same chances of recovery. This involves comparing similar age group, similar types of pneumonia, illnesses of similar duration and illnesses of similar severity as measured by bacteremia. If one applies these standards, one must have sufficient patients in each group so that the difference in death rate will be of such a magnitude that it can be said, with reasonable certainty, that the lowered death rate is due to the difference in therapy and not to a chance difference in the groups of patients selected for comparison. This evidence has been provided in the case of many types of pneumonia and for many age groups.

Such figures from various sources show what has been accomplished with serum therapy. In Massachusetts, according to Dr. Arthur P. Long of the Antitoxin and Vaccine Laboratory of the Massachusetts Department of Public Health, from July 1, 1938, to April 4, 1939, there were 199 patients under 60 years of age, with fourteen deaths, or a mortality of 7 per cent. In the Boston City Hospital, Dr. Maxwell Finland, using both horse and rabbit serum, lost no patients under 40 years of age. There were thirteen patients with bacteremia, with three deaths, a mortality of 23 per cent. The excellent results achieved in Pittsburgh, reported by Dr. I. Hope Alexander, in which the death rate was halved by the use of serum, are shown in figure 5.

Because at the present time chemotherapy, represented by sulfapyridine, offers assistance in the therapy of the pneumonias, it is important to contrast the advantages and disadvantages of the two types of therapy, as in the accompanying tabulation.

Serotherapy, which primarily fortifies the patient, has these advantages:

Antibody neutralizes capsular substance which either is already present in the body or develops during several days when sufficient serum is given.

Pneumococci are not dissolved or phagocyted unless they are sensitized by antibody. This may be autogenous or injected when vicariously produced in horses or rabbits.

Pneumococci have their virulence reduced when grown in the presence of antibody.

The disadvantages are as follows:

Serum administered must be specific for the infecting type.

Some types, especially those which produce a very large amount of antibody, such as pneumococcus type III, are resistant to serum.

Serum must be given intravenously and requires devotion on the part of the physician.

Though unfavorable reactions may be forestalled, there is always the possibility of anaphylaxis, thermal reactions and serum sickness.

Serum therapy is expensive.

Determination of the ultimate places to be assigned serum therapy and chemotherapy must wait on further studies.

62 West Eighty-Seventh Street.

CHEMOTHERAPY OF PNEUMOCOCCIC PNEUMONIA

CLINICAL LECTURE AT ST. LOUIS SESSION

COLIN M. MacLEOD, M.D.

NEW YORK

The ideal chemotherapeutic agent may be defined as one which, by inhibiting certain vital functions of the invading micro-organism or neutralizing its products, terminates the disease without causing any toxic effect on the host. This definition presupposes that the point of attack must be on a specific function or structure unique to the micro-organism, so that the tissues and organs of the host escape the toxic action.

Ethylhydrocupreine (optochin) was introduced by Morgenroth and Levy¹ in 1911 for the treatment of pneumococcal infections, after study of numerous other quinine derivatives. A good deal of enthusiasm followed the early experimental results and ethylhydrocupreine was used in the treatment of human pneumonia. However, the observations of Moore and Chesney² led to the conclusion that the use of ethylhydrocupreine in the treatment of pneumonia could not be recommended since it was impossible to administer an amount sufficient to achieve an effective concentration in the blood stream without subjecting the patient to the danger of toxic effects, of which amblyopia was the most frequent. Other quinine derivatives have since been recommended but up to the present time not one has had widespread clinical use.

The report by Domagk³ in 1935 of the therapeutic action of a sulfonamide compound on infections due to the hemolytic streptococcus led to the use of related compounds in the treatment of pneumococcal infections. Sulfanilamide was the first of these derivatives to be extensively used but its effect on experimental pneumococcal infections was found to be relatively small.

The most promising sulfonamide derivative, sulfapyridine, was introduced in England in 1938. The first report by Whitby⁴ on the use of this drug in experimental pneumococcal infections of mice showed such striking results that little time was lost in applying the experimental results directly in the treatment of pneumococcal infections of man. It is difficult to say at present how much the early enthusiasms may have to be tempered in the light of further experimental and clinical observations. However, it seems quite certain that the use of sulfapyridine is a distinct advance in the therapy of pneumococcal infections.

MODE OF ACTION

The mode of action of the sulfonamide group of drugs on different species of bacteria is poorly understood. Sulfanilamide exerts a bacteriostatic effect on susceptible micro-organisms, but its mode of action has not been fully elucidated. It has been postulated that sulfanilamide achieves its bacteriostatic effect by the

inhibition of certain enzyme systems of the bacterium, thus interfering with cell nutrition. On the other hand, it has been suggested that the drug combines with some essential growth substance, which then ceases to be available to the micro-organism. A somewhat different hypothesis has been advanced by Locke and his associates⁵ based on the observation that sulfanilamide when oxidized by ultraviolet rays exerts an anticalase effect. From this point of view the action of sulfanilamide is indirect, depending on the accumulation of hydrogen peroxide when catalase is inhibited. In the case of micro-organisms such as the pneumococcus or the hemolytic streptococcus, which do not possess demonstrable catalase activity, the bacteriostatic effect would then depend on the inhibition of catalase in the tissues and fluids of the host or in the medium in which the organisms are growing, thus permitting hydrogen peroxide to accumulate and exert a bacteriostatic effect. While this may be one of the systems affected by sulfanilamide or sulfapyridine, it would not appear to be the sole one so inhibited, since sulfapyridine will restrain the growth of pneumococci in a medium which does not contain demonstrable catalase.

DEVELOPMENT OF "SULFAPYRIDINE FASTNESS" IN VITRO

The action of sulfapyridine on the pneumococcus was believed at first to be on the capsule.⁶ The theory was advanced that in the presence of the drug the pneumococcus became deprived of its capsule and, denuded of this protective covering, became a ready prey for the phagocytes. This view has now been generally abandoned. We have been unable to confirm the observation that pneumococci in the sputum of patients treated with sulfapyridine lose their capsules and become avirulent. Indeed, we⁷ have shown that pneumococcus type I can be adapted to growth in increasing concentrations of sulfapyridine until finally it will multiply freely in concentrations of the drug which inhibit the growth of organisms not so accustomed. Throughout the procedure of adaptation the pneumococcus retains not only its type-specific capsule but its virulence as well. This "drug-fast" strain, unlike the parent strain from which it was derived, does not respond to the therapeutic effect of sulfapyridine in experimental infections. However, the "sulfapyridine-fast" strain is fully susceptible to the therapeutic action of type-specific antipneumococcus serum. In table 1 are shown the results of treatment with sulfapyridine and specific antiserum on the experimental infections of mice with the "sulfapyridine-fast" and parent strains of pneumococcus type I.

From the results shown in table 1 it can be seen that, although mice are protected by type I serum against fatal infection with both the parent and "drug-fast" strains, sulfapyridine has no curative effect on infections with a drug-fast strain. The acquisition of "sulfapyridine fastness" by a strain of pneumococcus type I takes place without alteration in the morphology, type specificity or virulence of the organism. "Sulfapyridine fastness" acquired by pneumococcus type I under these circumstances is relatively permanent.

After forty serial transfers in broth not containing the drug, "fastness" is retained. Similarly "fastness" is still present after fifteen passages in untreated mice.

DEVELOPMENT OF "SULFAPYRIDINE FASTNESS" IN VIVO

More recently we have been able to demonstrate that fastness to sulfapyridine may be acquired by pneumococcus type I in the animal body as well as during cultivation in the test tube. Mice were infected with pneumococcus type I and treated with sulfapyridine in dosage sufficient to prolong life but insufficient to bring about recovery. After three passages through mice which were treated in this manner, the strain of pneumococcus was found to be "sulfapyridine fast." Mice infected with the strain, rendered "drug fast" in vivo, died despite treatment with sulfapyridine in dosage sufficient to bring about recovery of all mice in the control group infected with the parent strain of pneumococcus type I.

Variations in susceptibility to the bacteriostatic action of sulfapyridine have been noted by MacLean, Rogers and Fleming.⁸ These investigators were able to show in addition that a strain of pneumococcus type VIII which was relatively insensitive to the action of sulfapyridine could be made even more insensitive to the drug by repeated passage of the strain in mice treated with sulfapyridine.

METABOLISM OF "SULFAPYRIDINE-FAST" AND PARENT STRAINS OF PNEUMOCOCCUS TYPE I

Studies of the metabolism of the "sulfapyridine-fast" and parent strains of pneumococcus type I have revealed certain differences. In aerobic cultures the parent strain of pneumococcus produces large amounts of hydrogen peroxide,⁹ whereas the "sulfapyridine-fast" strain forms little or no hydrogen peroxide under similar condi-

TABLE 1.—Results of Treatment with Sulfapyridine or Type I Serum of Mice Infected with Parent Strain and "Sulfapyridine-Fast" Strain of Pneumococcus Type I*

Treatment	Infecting Dose,† Cc. Culture	Result	
		Parent Strain	"Sulfapyridine-Fast" Strain
Type I antipneumococcus rabbit serum unconcentrated 0.2 cc.	10 ⁻²	SSSS†	SSSS
	10 ⁻³	SSSS	SSSS
	10 ⁻⁴	SSSS	SSSS
Sulfapyridine 4 doses of 30 mg. each	10 ⁻²	SSS	DDD
		SSS	DDD
		SSS	DDS

* All mice were infected intraperitoneally. Sulfapyridine was administered by stomach tube in 30 mg. doses. The first dose was given immediately following infection, the second five hours later. Subsequent doses of 30 mg. were given at daily intervals. The serum used was type I unconcentrated antipneumococcus rabbit serum. Serum and culture were mixed in the syringe immediately before intraperitoneal injection.

† The virulence of both cultures was such that untreated mice infected with 10⁻⁷ or 10⁻⁸ cc. died within forty-eight hours.

‡ S indicates survival; D indicates death.

tions.¹⁰ The production of hydrogen peroxide by cultures of pneumococcus may be determined readily by cultivating the organisms on the surface of blood agar which contains benzidine, according to the technic

described by Penfold.¹¹ Strains which produce large amounts of peroxide form jet-black colonies, whereas strains forming small amounts of peroxide cause much less discoloration of the medium.

Moreover, we¹⁰ have recently found that the "sulfapyridine-fast" strain has lost in great part its ability to dehydrogenate certain three-carbon com-

TABLE 2.—Dehydrogenase Activity of Parent and "Sulfapyridine-Fast" Strains of Pneumococcus Type I*

Substrate Final Concentration	Parent Strain		"Sulfapyridine-Fast" Strain	
	Without Sulfapyridine	Sulfapyridine 1:8,000‡	Without Sulfapyridine	Sulfapyridine 1:8,000
Dextrose M/140.....	++++†	++++	++++	++++
Glycerol M/80.....	++++	+	—	—
Sodium pyruvate M/80.....	++++	+	—	—
Sodium lactate M/80.....	++++	—	—	—
No substrate.....	—	—	—	—

* Each tube contained 0.5 cc. of 0.002 M methylene blue in M/20 phosphate buffer pH 7.6; 0.1 cc. of plain broth as a source of coenzymes; 0.5 cc. of the appropriate substrate; 1.0 cc. of the suspension of pneumococcus cells. The final volume was brought to 4.0 cc. in each case by the addition of M/20 phosphate buffer pH 7.6. The tubes were sealed with a layer of petrolatum and incubated at 37 C.

† ++++ indicates complete reduction of methylene blue after one hour at 37 C. — Indicates no reduction of methylene blue.

‡ One cc. of a neutral solution of sulfapyridine 1:2,000 added as indicated, making a final concentration of 1:8,000.

pounds (glycerol, pyruvate, lactate). The ability to utilize dextrose remains undiminished.

The technic used in demonstrating the differences in the metabolism of the parent and "sulfapyridine-fast" strains was the estimation of the reduction of methylene blue by "resting" cell suspensions¹² of the microorganisms in the presence of the various substrates, as shown in table 2.

In extension of these results we have observed that sulfapyridine added directly to cell suspensions of the parent strain of pneumococcus type I inhibits the dehydrogenation of these same substances. Thus it would appear that the bacteriostatic effect of sulfapyridine on the pneumococcus may be due in part to inhibition of an enzyme or enzymes concerned in the utilization by the bacterial cells of these substrates—glycerol, pyruvate and lactate.

EFFECT IN THE ANIMAL BODY

In the animal body sulfapyridine exerts a bacteriostatic effect on the pneumococcus¹³—a reflection of the effect which occurs in the test tube. If one considers the course of events in recovery from pneumococcal pneumonia it will be seen that in many cases bacteriostasis may be all that is required for a favorable outcome to occur. Spontaneous recovery from pneumococcal pneumonia is usually associated with the development by the host of specific antibodies. At the risk of oversimplification it may be said that, if the pneumococcus is able to multiply more rapidly than the patient is able to produce specific antibody, the patient will die. However, if a bacteriostatic agent is used, the organisms multiply more slowly while the rate of antibody production is undiminished; hence the acute course of the disease may be shortened. There is no good evidence at present that the body can rid itself of virulent pneumococci by phagocytosis unless the organisms are first

sensitized by specific antibody. Even virulent pneumococci which have been killed by heat are not phagocytosed unless they are first sensitized.

If a particular strain of pneumococcus happens to be a good antigen in a certain host species, injection of the organisms of such a strain will cause a good antibody response. On the other hand, if the strain is a poor antigen the antibody response will be poor. This is illustrated by the antigenicity in the mouse of pneumococci types I and III. Type I is a good antigen, whereas type III is a relatively poor antigen. If groups of mice are infected intraperitoneally with 10^{-2} cc. of fully virulent broth culture of these strains and treated with sulfapyridine, the survival rate parallels in each case the immune response elicited by a single intraperitoneal injection of the same amount of heat-killed organisms of the respective strains in other groups of mice. The results of a series of such experiments are shown in table 3.

Mice injected with 10^{-2} cc. of culture of pneumococcus type I, and treated with six doses of 30 mg. each of sulfapyridine over a five day period, show a survival rate of from 95 to 100 per cent. Similarly, from 95 to 100 per cent of mice given a single intraperitoneal injection of 10^{-2} cc. of heat-killed organisms of the same culture showed active immunity when tested five days later by infecting intraperitoneally with 1,000 lethal doses of homologous culture.

In the case of pneumococcus type III a similar relationship was found to exist between the immune response and the survival rate following sulfapyridine therapy, although in this case both are very low. Ten per cent or less of mice survived which were infected with 10^{-2} cc. of culture and treated with the drug. The immunity induced in a comparable group of mice by a single injection of the same amount of heat-killed vaccine was of the same order.

It is also of great interest that, in this species of animal, treatment with sulfapyridine is necessary only for the period known to be required for the development of antibodies. Thus there appears to be a correlation not only between survival from infection and the antigenicity of the strain of pneumococcus but also between the time required for the host to develop anti-

TABLE 3.—Relation of Effectiveness of Sulfapyridine Therapy to Immunity Induced in Mice by Injection of Pneumococcus Vaccines

Pneumococcus Type	Infection with 10^{-2} Cc. Culture; Treated with Sulfapyridine; * per Cent Survival	Immunized with 10^{-2} Cc. Heat-Killed Culture;† No Sulfapyridine Given; per Cent Immune
Type I.....	95-100	95-100
Type III.....	0-10	0

* Mice were infected intraperitoneally. The virulence of both cultures was such that untreated mice infected with 10^{-2} or 10^{-3} cc. died within forty-eight hours. Treatment with sulfapyridine was carried out for five days, a total of 180 mg. of drug per mouse being given.

† Single immunizing dose of heat-killed organisms given intraperitoneally. Immunity tested five days later by infecting intraperitoneally with 1,000 lethal doses of homologous culture.

bodies and the length of time necessary to continue sulfapyridine treatment.

In his original communication Whitby⁴ pointed out that mice which recovered following infection with pneumococcus type I and treatment with sulfapyridine are immune to reinfection with the homologous organism, and we have confirmed this observation. Similarly Larson and his co-workers¹⁴ have observed the same

phenomenon in rabbits which recovered following intradermal infection with pneumococcus type II and treatment with sulfapyridine. McIntosh and Whitby¹⁵ have extended Whitby's earlier observations and conclude that administration of the drug to mice does not affect "the quality, quantity or speed of production of recognized specific antibodies."

TABLE 4.—Synergistic Effect of Sulfapyridine and Antipneumococcus Serum in Experimental Infection of Mice with Pneumococcus Type III *

Infecting Dose, Cc. of Culture	Amount of Serum, Cc.	Sulfapyridine Number of Doses	Number of Mice Infected	Number of Mice Surviving	Percentage Survival

10^{-2}	0.05	2	20	12	60

* Unconcentrated type III antipneumococcus rabbit serum and culture were mixed in the syringe immediately before intraperitoneal injection. The administration of sulfapyridine was as described in table 1.

SYNERGISM OF ANTIPNEUMOCOCCUS SERUM AND SULFAPYRIDINE

Since the participation of the active immune mechanism appears to play a considerable role in the successful action of sulfapyridine on experimental infections with the pneumococcus, it was of interest to determine whether synergism exists between the drug and the passive immunity conferred by the administration of specific antiserum.

Groups of mice were infected with pneumococcus type III and treated respectively with sulfapyridine alone, serum alone and the same amount of the two agents in combination. The dosage of serum and sulfapyridine when used alone was such that little or no protection was afforded against the infecting inoculum. The protocol of a typical experiment is shown in table 4.

The results presented in table 4 make it clear that type III antipneumococcus serum and sulfapyridine are synergistic, since amounts of each agent which used singly exert little or no protective action afforded protection to 60 per cent of mice when used in combination. The demonstration of synergism of the two agents in the treatment of infections due to pneumococcus type III is of particular interest, since the protective action of either agent alone in experimental infections of mice is distinctly less than that which occurs in infection with pneumococci of other types.

CLINICAL USE OF SULFAPYRIDINE

The numerous reports concerning the therapeutic effect of sulfapyridine in pneumococcal pneumonia have been uniformly favorable. Mortality rates of from 2 to 10 per cent in series of cases reported from various parts of the world indicate that the drug is effective in reducing the mortality rate. However, insufficient attention has been paid to the toxic effects of this chemotherapeutic agent.

Nausea and vomiting are frequent accompaniments of the administration of sulfapyridine. These reactions are unrelated to the dosage of drug or to the blood level. Since vomiting occurs in individuals to whom the drug has been administered parenterally, the effect would appear to be central, in addition to a possible local action on the stomach.¹⁶ Morbilliform skin rashes have

been reported, as well as numbness and tingling of the extremities.¹⁷ Cyanosis due to methemoglobinemia occurs, particularly if high blood levels of the drug are attained.

More serious toxic manifestations may appear, however, involving particularly the hemopoietic system and the urinary tract.

EFFECT OF SULFAPYRIDINE ON HEMOPOIETIC SYSTEM

The occurrence of acute hemolytic anemia in patients receiving sulfanilamide has been the subject of many reports, but as yet there is little information available concerning increased blood destruction in patients receiving sulfapyridine. During the routine administration of sulfapyridine to patients with pneumonia, hemolytic anemia occurred in two instances; consequently a study of the effect of this drug on hemolysis was undertaken.¹⁸ Estimation of the total urinary and fecal excretion of urobilinogen was used as an index of the rate of hemolysis, since by this means increases in the rate of blood destruction may be observed which might escape detection if only routine clinical procedures are used.

Of the twenty-six patients with pneumonia for whom estimations of urobilinogen excretion were made, six did not receive sulfapyridine and in none of these was there an increase in the excretion of urobilinogen. Twenty patients received sulfapyridine in total dosage varying between 4.5 and 81 Gm., and in eight of these the excretion of urobilinogen in stools and urine was increased from one and one-half to five times the normal amount. Acute hemolytic anemia occurred in three of these patients. However, in the twelve other patients who received sulfapyridine, the urobilinogen excretion was normal or only slightly increased. The total dosage of drug administered to patients in the latter group tended to be less than that given to patients who showed increased urobilinogen excretion.

Increased blood destruction does not appear to be a usual accompaniment of the acute infectious process itself, since in eighteen of the twenty-six patients studied the excretion of urobilinogen was within normal limits. The evidence indicates that hemolysis was due to sulfapyridine rather than to pneumonia itself and that increased blood destruction occurs more frequently following the administration of this drug than would be suspected unless special methods for its detection are used.

The occurrence of granulocytopenia in patients receiving sulfapyridine has been reported.¹⁹ This toxic effect occurs less frequently than hemolysis but is additional reason for making repeated blood examinations on patients who receive the drug.

EFFECT OF SULFAPYRIDINE ON THE URINARY TRACT

The solubility of sulfapyridine is less than that of sulfanilamide. This may account in part for the occasionally erratic absorption of the former drug and

also for irregularities in its excretion. Antopol and Robinson²⁰ have described the occurrence of calculus formation in the urinary tract of monkeys fed sulfapyridine. The same complication occurred also in rats and rabbits, although in the case of the last two species much larger dosage was required. Renal calculi have been observed likewise by Gross, Cooper and Lewis²¹ in rats that were fed sulfapyridine. The calculi described by both groups of investigators were found to be composed chiefly of the acetyl derivative of sulfapyridine.

Hematuria, aside from that occurring during hemorrhagic Bright's disease, has been observed in only two instances during the course of sulfapyridine therapy in this hospital. One of these patients, a man aged 21, suffered from typical renal colic with hematuria shortly after discontinuing the drug. A calculus was not visualized by x-ray examination and the symptoms gradually disappeared. According to Antopol and Robinson²⁰ the concretions of sulfapyridine and its acetylated derivative which occur in the urinary tract of monkeys are not usually seen in roentgenograms although they may become radiopaque because of overlayering with calcium salts.

Southworth and Cook²² have reported the occurrence of azotemia in two of three patients who developed hematuria during sulfapyridine administration. In addition there was acute abdominal pain, which was believed to be of renal and ureteral origin. On cessation of drug therapy and with the forcing of fluids, these signs and symptoms cleared rapidly.

Depression of renal function may occur, however, in the absence of hematuria. In two patients treated with sulfapyridine we have observed a temporary depression of the urea clearance to critical levels associated with azotemia, although hematuria was not present in either instance. With discontinuance of drug administration there was a rapid improvement in kidney function with disappearance of azotemia, and complete recovery apparently ensued. The studies of Farr and Abernethy²³ on renal physiology in lobar pneumonia indicate that depression of kidney function is not a usual accompaniment of this disease. Indeed, in the experience of these authors, patients below the age of 40 showed a marked elevation of the urea clearance during the acute phase of the disease, with persistence of the increased function for about one month. In the older age group the urea clearance showed little change.

The impression that the diminution of the urea clearance which occurred in the two cases noted may have been an expression of sulfapyridine toxicity is strengthened by the fact that acute hemorrhagic Bright's disease has developed in two other patients who received the drug.

REPORT OF CASES

CASE 1.—A white woman aged 25, whose past history was noncontributory, was admitted to the hospital on the eighth day following the onset of type III pneumococcus pneumonia. Consolidation of the right middle, right lower and left upper pulmonary lobes was present. The temperature was 104.2 F., pulse rate 132 and respiratory rate 40. The blood culture was sterile. The blood pressure was 112 systolic, 66 diastolic. Urinalysis gave normal results. Erythrocytes numbered 3,790,000, hemoglobin was 74 per cent, and leukocytes numbered

21,450, of which 84 per cent were polymorphonuclear cells. Sulfapyridine treatment was commenced shortly after admission, a total of 25 Gm. being given by mouth in the ensuing four days. Nausea and vomiting occurred after 4 Gm. of drug was given. The free sulfapyridine level in the blood was 12.6 mg. per hundred cubic centimeters thirty-six hours after the drug was started, and with this there was associated a marked diminution in the volume of urine excreted. The patient's temperature and pulse rate fell to normal on the day following admission and agglutinins for the type III pneumococcus were demonstrable in her blood serum. The skin reaction with the type III pneumococcus polysaccharide was positive at this time. The respiratory rate remained markedly elevated for four days after the crisis.

The urine output remained low despite a large intake of fluid, and with this there was associated pain across the upper abdominal area anteriorly, together with drowsiness and puffiness of the face. The blood pressure was 142 systolic, 88 diastolic. Urinalysis showed a trace of albumin, with an occasional granular cast but no red cells.

Five days after sulfapyridine was discontinued the blood level of the free drug was 0.8 mg. per hundred cubic centimeters and the urine showed 12.4 mg. The urine volume on this day was only 300 cc. The blood urea nitrogen level was 61 mg. Two days later the blood urea nitrogen had fallen to 33.6 mg. and urea clearance showed the kidney function to be 62 per cent of normal.

From the third to eighth hospital days the excretion of urobilinogen in stools and urine increased markedly and was associated with a fall in the red cell count and the hemoglobin level. On the twelfth hospital day the red blood cell count was 2,000,000 and hemoglobin 50 per cent; consequently a transfusion of 500 cc. of whole uncitrated blood was given. No reaction occurred during or after transfusion.

Edema of the face continued and the blood pressure rose to 162 systolic, 92 diastolic on the day before transfusion was given. The urea clearance was 54.8 per cent. The plasma albumin level was 2.69 mg. per hundred cubic centimeters and the plasma globulin 2.69 Gm. The urine showed 1.4 Gm. of protein excreted in twenty-four hours and large numbers of granular casts. Centrifuged specimens of urine showed only from 2 to 4 red blood cells per high power field.

Bilateral pleural effusion occurred with a rise in temperature and marked elevation of the pulse rate. Thoracentesis was performed on two occasions with the withdrawal of large amounts of sterile pleural fluid.

Diminution in urinary output persisted for twenty days, and was followed by a period of diuresis with disappearance of edema and upper abdominal pain. Four weeks after the onset of the renal complication the urea clearance had risen to 90 per cent of normal. The urine continued to show a trace of albumin and a few granular casts for one month after the urea clearance had returned to normal, but on discharge four months after admission the urine was normal. The blood pressure was 128 systolic, 78 diastolic. The red blood count was 4,840,000 and hemoglobin 96 per cent. The urea clearance was 96.3 per cent of normal.

CASE 2.—A white woman aged 43 was admitted to the hospital on the day following the acute onset of type III pneumococcus pneumonia which involved the left lower lobe. Her past history was noncontributory. The temperature was 104 F., pulse rate 120, respiratory rate 36. The blood culture was sterile. Erythrocytes numbered 4,200,000, hemoglobin 78 per cent, leukocytes 20,400, of which 90 per cent were polymorphonuclear cells. The blood pressure was 130 systolic, 68 diastolic. Urinalysis showed a faint trace of albumin. Sulfapyridine therapy was commenced shortly after admission, a total of 12 Gm. being given over a three day period. Nausea and vomiting occurred but were not severe. The highest blood level attained was 10.7 mg. per hundred cubic centimeters of the free drug on the last day of administration. In addition to sulfapyridine the patient was given 100 cc. of unconcentrated type III antipneumococcus rabbit serum twelve hours after admission. No toxic reaction due to serum occurred. The skin reaction with the type III polysaccharide, which was negative on admission, became positive following serum; consequently no further

antibody was given. Temperature, pulse and respiratory rates reached normal thirty-six hours after admission and remained normal for forty-eight hours, when the fever returned, associated with severe pleural pain. The administration of sulfapyridine was recommenced and between the seventh and eleventh days following admission an additional 13 Gm. of the drug was given. The skin reaction with the type III polysaccharide remained positive during this time. A massive left-sided pleural effusion occurred.

Examination of the urine on the day following withdrawal of sulfapyridine showed many granular casts as well as numerous red cells and pus cells. A heavy trace of albumin was present.

The patient complained of upper abdominal pain and began to show increasing pallor associated with a fall in the red blood count to 3,000,000 and of the hemoglobin level to 64 per cent. Concurrently edema of the face and extremities appeared and the output of urine diminished sharply. The patient's condition was fairly satisfactory until the twenty-fifth hospital day, when she suddenly developed acute cardiac failure with gallop rhythm and pulmonary edema, a markedly enlarged liver and rapidly increasing generalized edema. The urine showed 14.4 Gm. of protein per liter with numerous pus cells, red blood cells and granular casts. The urea clearance was 6.4 per cent of normal with blood urea nitrogen of 71.6 mg. per hundred cubic centimeters. The blood pressure was 184 systolic, 104 diastolic.

The patient's subsequent course was very stormy, owing to the mixed picture of heart failure and acute hemorrhagic Bright's disease with uremia. After two weeks, improvement in kidney function began to appear with a gradual loss of edema and improvement in the cardiac condition.

Prolonged convalescence was necessary, but after three months the patient became edema free, and kidney function, as measured by the urea clearance test, had risen to 37.7 per cent of normal.

In the first of these patients the earliest symptoms of acute nephritis occurred during the time sulfapyridine was being administered. Although moderate dosage was used, the blood levels of sulfapyridine were abnormally high, associated with a sharp drop in urine output, which occurred within twenty-four hours after beginning treatment with the drug. Five days after the drug was withdrawn the patient's blood still contained 0.8 mg. per hundred cubic centimeters of free sulfapyridine. The occurrence of edema, the elevation of blood pressure and gross abnormalities in the urine were of gradual rather than of acute onset. As far as could be determined, the renal function returned to normal in two months.

The course of events in the second patient likewise differs somewhat from the typical picture of acute nephritis complicating an acute infection in that the onset was gradual rather than sudden. The first urinary signs appeared on the day following the discontinuance of sulfapyridine therapy and for the succeeding fourteen days the symptoms increased in severity until the final explosive onset of acute uremia associated with heart failure.

Only one patient (patient 2) received antipneumococcus serum treatment in addition to chemotherapy. The use of serum has not been associated in our experience with renal complications.

Both patients have recovered from the acute phase of nephritis, the first apparently completely, but in the second case only partial recovery has taken place during the four months since the onset of nephritis.

COMMENT

It may appear that undue stress has been laid on the toxic effects of sulfapyridine. However, it seems important that such effects should be generally recognized so that due caution may be observed in the clinical use of

this valuable chemotherapeutic agent, not only as applied in the treatment of pneumonia but in other diseases as well.

Sulfapyridine gives promise of reducing the death rate from pneumococcic pneumonia and present indications make it seem probable that an even greater reduction in the mortality rate can be accomplished if the drug is used in conjunction with type-specific antipneumococcus serum.

In the opening paragraph of this paper the ideal chemotherapeutic agent was defined as "one which, by inhibiting certain vital functions of the invading micro-organism or neutralizing its products, terminates the disease without causing any toxic effect on the host." From this point of view sulfapyridine does not fully attain the ideal, since toxic effects of greater or lesser degree are not infrequent accompaniments of its clinical use. Moreover, this powerful drug may not necessarily inhibit the vital functions of the ordinarily susceptible invading micro-organism, since the virulent pneumococcus has the capacity both in vivo and in vitro to adapt itself so that the drug does not affect its rate of multiplication, virulence or specific immunologic structure.

OXYGEN THERAPY

INDICATIONS AND METHODS OF APPLICATION;
RELATION TO OTHER THERAPY

CLINICAL LECTURE AT ST. LOUIS SESSION

M. A. BLANKENHORN, M.D.

CINCINNATI

Cyanosis is the main and only important indication for oxygen therapy in pneumonia. While it can be said in theory that cyanosis exists in some degree in every patient with pneumonia, it does not follow that oxygen is always indicated nor is there any justification for the routine use of oxygen to prevent cyanosis.

Cyanosis is a difficult sign to evaluate quantitatively and, since that is exactly what must be done to decide about oxygen therapy, there is a tendency to use it needlessly. This tendency becomes very pressing when the prognosis looks bad and there is not very much to be done about it. Now that there is at hand for most pneumococcic pneumonia a good remedy, the need for oxygen is definitely reduced. I find in our hospital at Cincinnati that more of our patients have got well and that we have used much less oxygen since we began the use of serum or sulfapyridine in the early stages of pneumonia.

The exact therapy of pneumonia with oxygen has been developed by keeping patients in oxygen-filled rooms for continuous treatment, which treatment is tested by measuring the actual oxygen content of arterial and venous blood. With this experience some of the guesswork goes out and it can be seen that severe anoxemia does occasionally occur in the early stages of pneumonia, oftener in the late stages, and that oxygen sometimes relieves this anoxemia. Severe anoxemia is most likely to occur when many lobes are consolidated; when the respirations become rapid and shallow, i. e., above forty per minute; when there is moisture in much of the bronchial tree, and when there is wheezing.

These circumstances can bring on serious oxygen want which may initiate many symptoms that resemble the toxic effects of infection; viz., steadily rising pulse rate with finally falling diastolic blood pressure, headache, dimness of vision, mental disturbances such as delirium, and coma. Oxygen want may cause or increase abdominal distention, also vomiting. When oxygen is successfully given, many, sometimes all, the distressing signs and symptoms disappear in a few hours and the treatment then is life saving.

Oxygen treatment may not be successful in relieving anoxemia for a number of reasons other than reasons of technic. It cannot succeed if too much lung is consolidated or obstructed by exudate. It cannot succeed if the circulation is failing or if there is toxic depression of the respiratory center by infection or drugs. Since none of these causes of failure are easily apprehended, the technic of administration of oxygen must be carefully ordered and practiced by the physician to avoid failure that can be avoided. Important points are these: The supply to the patient must be continuous and abundant, so that only large cylinders are satisfactory; these must be equipped with reducing valves to assure steady flow and flow meters are very useful as well; the inhalation device must be comfortable and must not hamper the free escape of carbon dioxide and moisture. There are numerous devices that are Council accepted. Tents, face masks and nasal tubes can all be made to serve satisfactorily, but they all require skilful and understanding care such as is rarely given by nurses or attendants. They all must be supervised by the doctor, who understands both the disease and the treatment.

Tents are the most expensive, troublesome and difficult to operate but are the most successful generally, except of course the oxygen chamber. Tents are best run by experts, such as the anesthesia department or gas therapy service in large hospitals. I have found that hospital assistant residents do the job very well in the Cincinnati General Hospital and that they learn a lot about the physiology of respiration by doing that service. Some tents require a gas washer of soda lime to take out the carbon dioxide. This greatly adds to the cost and trouble. Other tents rely on cooling and drying the circulating air with large ice chambers, and much ice is needed for air conditioning. This cooling and drying to take out carbon dioxide often contributes much to the comfort of the patient. Tents should usually have from 35 to 40 per cent oxygen but may be run for a long time at 60 per cent oxygen. Tents provide a high concentration of oxygen as well as a cool, dry atmosphere, which many patients enjoy if the tent is right. A hot tent, not properly cooled and cleared of carbon dioxide, is a terrible thing to a conscious patient; but there is no need for a tent ever to be uncomfortable. A gas tester is necessary to keep tent service up to this standard. Delirious patients sometimes fight the tent and win, for tents are not tough. In this circumstance the doctor must do some skilful guessing to decide about restraining the fighter or narcotizing him. The first procedure runs up the oxygen need possibly more than it will be helped by the tent; the latter choice depresses the respiration, sometimes increasing the cyanosis. The doctor must keep his eye on cyanosis and try the various chances.

Face masks and face tents in my hands are almost as bad as tents in arousing the fight in a delirious patient. Nasal tubes or catheters are the best for this patient usually.

Face masks are not suited to continuous use, such as the pneumonia patient needs, if the mask is closed. If the device is open to allow unhampered flow of expired air, it becomes a face tent of sorts and I think that with care to details, especially adequate oxygen flow, this arrangement will work; but I have had no real satisfaction in their use. The purpose of such a device is to retain a rich atmosphere during expiration so that when inspiration comes the inrush of room air through the mouth or nose will not dilute the stored gas too greatly.

Nasal catheters are used in many instances, even when tents are at hand. Such an arrangement is simple and costs little, but large cylinders with flow meters are needed as for tents. Catheters are sometimes tolerated by delirious patients who fight the tent. Success of nasal catheters depends on care in placing the catheter tip and keeping it there. The catheter becomes a discomfort for several causes, mostly preventable. If the catheter wiggles about with head motion or bed motion, this is overcome by holding it down to the face with adhesive tape. If the inflow is too fast through a single perforation in the catheter wall, a "hot spot" develops; this is overcome by moving it about and by humidifying the gas; also by having plenty of openings. Catheters may fail to deliver enough gas if the tip is not near the pharynx. In this circumstance the soft palate may obstruct the inflow and the gas then goes in one nostril and out the other. If the patient breathes through the mouth and the method of inspiration is quick, the inrush of room air dilutes the gas and the whole result is a weak mixture. I know of no way to overcome this difficulty entirely if the patient will not tolerate having his mouth closed with a piece of moist gauze taped over the mouth for a flutter valve. When the catheter tip is well in the oropharynx so that the entire oropharynx is entirely filled with oxygen, this dilution effect is diminished. The dilution effect is also less when the volume of each breath is not great; hence the catheter flow can supply the entire inspiratory volume and even more in rapid and shallow breathing. In some circumstances 40 per cent of oxygen or more has been provided in respired air through the catheter. The catheter should be replaced by a clean one every twelve hours or less. It should be greased with oil that will not evaporate, as with liquid petrolatum, and the nasopharynx sprayed with oil. This protects the mucous membranes from the drying effect that eventually burns or smartens painfully, causing the "hot spot." With nasal catheters the oxygen dosage must be regulated with the flow meter; but no one can prescribe the liters per minute that will relieve cyanosis. A good practice is to start the flow at as high a figure as the patient will endure, and 10 liters is about the maximum. If this is adequate, the color may improve in a few minutes. When there is a definite change, the flow may be reduced; from 6 to 8 liters per minute will generally be tolerated and the cost at this rate of flow is not great. If 10 liters per minute does not help the color of the patient in an hour, one should try placing the catheter tip lower into the oropharynx—at a spot below the palate but where the swallowing reflex will not interfere. Two catheters, one in each nostril, may be used if the patient breathes through the mouth: the flow to each catheter can then be reduced to a tolerable rate.

Oxygen therapy to be useful must be continuous as long as cyanosis develops if the treatment stops. It is not harmful to stop it for a test of doing without, except in widespread pneumonia when there is much

moisture in the air passages. Here oxygen is helpful and very necessary. Some patients seem to become habituated to a rich atmosphere of oxygen, but this condition does not develop in short time nor has it been described in lobar pneumonia.

With the best of technic oxygen may in certain cases be life saving to the pneumonia patient, but it is very difficult to prove the point. Where oxygen has been most intelligently used and checked with blood measurements, this form of pneumonia therapy is always regarded as of minor importance in lobar pneumonia as compared with serum or chemotherapy. In suffocating pneumonia, such as in capillary bronchitis; in wet hemorrhagic pneumonia, as in influenza; in pneumonia after corrosive gases; in asthma complicated by pneumonia, or in pneumonia complicated by acute bronchiolar spasm—in these forms oxygen may be the most important item in treatment.

Properly administered, oxygen inhalation is compatible with any other form of treatment. It should never substitute for specifics when such are at hand.

Cincinnati General Hospital.

GENERAL THERAPY OF PNEUMONIA

ROGER I. LEE, M.D.

BOSTON

Three spectacular therapeutic procedures in pneumonia, namely oxygen, serum and chemotherapy, especially in judicious combination, bid fair to rob pneumonia of much of its terror. Certainly the death rate from pneumonia will be strictly reduced. At this moment no man can say how much that reduction, albeit certainly great, will be and furthermore no man can say whether or no the immediate or remote future will bring further developments of these therapeutic agents or new agents.

At this date, May 1939, it is certainly premature to discard all other therapeutic devices and measures in pneumonia, and in all likelihood it will always be foolhardy to treat the disease pneumonia or any one of its symptoms exclusively and to ignore the patient. In truth the patient is the container of the disease. He then becomes the battleground of what formerly nearly always was and even now often is a titanic struggle. As the opposing forces line up and get into action and as the battle begins and goes on, the unfortunate patient or container of this devilish battleground is badly shaken and racked. Furthermore, during this turmoil the patient has functional obligations, including the transport of oxygen, serum and drugs to carry on. Moreover, according to our present beliefs the patient himself must actively participate in the battle against the invading enemy if cure is to result, no matter how specific drugs and serums seem. The patient who is an inert container will die.

Essentially the general management of a case of pneumonia consists in the conservation of strength. Rest and quiet are the prime considerations. There should be no delay in putting the patient, and that includes the suspects, to bed. Within the first twenty-four hours a patient may probably be moved without undue increase of risk in an ambulance (not an automobile) to a hospital, provided the distance is not over a few miles and provided the bed to bed journey

Read in the Panel Discussion on Pneumonia, Medical Division, General Scientific Meetings, at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 16, 1939.

THERAPY OF PNEUMONIA—LEE

1412

is accomplished with the smoothest possible arrangements. However, any move does actually increase the risk somewhat and after forty-eight hours of the disease the increase in risk to the patient is considerable. Therein often is required a wise balancing of benefits and hazards with the prejudice toward non-transportation after forty-eight hours.

In the home the so-called hospital regimen must be established, including a hospital bed and continuous nursing. By rest I mean the elimination of any unnecessary physical activity. The patient should not feed himself or give himself a drink. He should not turn over by himself. By quiet I mean the elimination of any unnecessary outside disturbance to the patient. This obviously includes visitors and also includes any unnecessary medical manipulations and examinations. Blood counts, blood cultures, physical examinations and x-ray examinations must be carefully organized in advance and carried out with precision and dispatch. Likewise the somewhat elaborate and technical procedures as intravenous serum therapy or intravenous fluid therapy or subcutaneous medication or fluid administration should be prepared as far as possible outside the room.

Probably next in importance is the supply of an adequate amount of fluid to the patient. On this subject there is a wide diversity of opinion. My own view is that the intake should suffice to keep the urinary output in the neighborhood of 50 ounces (3 pints, or 1,500 cc.). Less than this I regard as insufficient and much more than this as creating unnecessary work for the heart, circulation and kidneys. Some patients who sweat a good deal may have difficulty in getting in an adequate amount of fluid. Other patients may have marked gastric disturbances in the early days of the disease. Perhaps a majority of patients who take sulfapyridine have gastric symptoms to a greater or less degree. Some of these patients will require fluid by some other route, although skilful nursing with a shrewd selection of fluid, e. g. the use of very weak, rather hot plain tea, and the avoidance of egg-nogs and of excessive fruit juices will diminish the number of patients who must be disturbed either by intravenous or by subcutaneous fluids. If there is vomiting and acidosis one may lean toward intravenous saline solution with dextrose, but my personal preference based on physiologic grounds is for the subcutaneous route. The desirability of avoiding intestinal disturbance, either distention or diarrhea, both of which are well known bugaboos in pneumonia, usually decides against using the intestinal route for fluid.

In the average case of pneumonia in the acute stage, little attention need be paid to the caloric requirements. It is imperative to get in fluid and highly desirable to avoid distention or diarrhea. Hence a low residue diet without much milk meets the requirements. Obviously food requiring chewing should be avoided, but minced chicken, mashed potato, soft toast, soft cereals, eggs, ice cream and apple sauce indicate the range of possibilities. With distention milk may be further reduced and cream added. Usually a mild vegetable laxative is given each night and an enema if necessary every other day.

The evidence is clear and strong that sodium chloride is diminished during pneumonia, through perspiration and in the pulmonary exudate. Therefore the salt in the diet is increased and frequently, if capsules are well tolerated, salt is so given in 5 or 10 grain (0.3 or 0.65 Gm.) capsules up to 60 grains (4 Gm.) a day.

While there is some evidence that ascorbic acid and probably some of the other vitamins are diminished in pneumonia, at this time and for this discussion it seems better to consider vitamin and iron therapy in the management of the convalescence and not of the disease.

Over the years the old saying has been repeated "The disease is in the lungs but the danger is in the heart." Translated into the terminology of today and without attempting a precise explanation of the complicated pathologic physiology, one may say simply that the danger lies in circulatory failure. After a very thorough trial the evidence is definitely against the value of routine digitalis therapy in pneumonia. In a previously undamaged heart and circulation, digitalis and its group are but rarely indicated. The indications for the exhibition of digitalis are the usual indication of an incompetent heart. The heart is seemingly stimulated early in the disease by the circulating toxins or the fever or both. Later in the disease those patients who seem likely candidates for cardiac incompetence from previous cardiac damage, hypertension or old age may be benefited by digitalis. A not uncommon cardiac symptom in patients beyond middle age and rarely before is the occurrence of a tachycardia, paroxysmal in type, of the nature of flutter or fibrillation. Such attacks usually cease spontaneously, but quinidine or digitalis or both are ordinarily indicated.

There may be, of course, in pneumonia a wide variety of incidental symptoms. Many patients have a previous familiarity with various members of the salicylate group. If sweating is not greatly increased and if the stomach is not disturbed, some comfort, ease of headache and of general malaise and diminution of fever may be attained by the moderate use of the salicylate group. The pleuritic pain, usually early, may be distressing. A swathe is better than drugs. The salicylates may of course be tried. The exhibition of large doses of opiates has been regarded as contraindicated in pneumonia and with a good deal of supporting physiologic evidence. On the other hand the desideratum of rest is so important that I feel no hesitation in using frequent small doses of morphine subcutaneously. By small doses I mean as small as $\frac{1}{2}$ or $\frac{1}{16}$ grain (0.002 or 0.004 Gm.). This is also very useful in combating restlessness. The oral administration of morphine, codeine and opium has the objection of being decidedly constipating.

Fortunate indeed is the patient with pneumonia whose restlessness is controlled by one-fourth grain (0.016 Gm.) of phenobarbital a few times a day and who sleeps soundly with phenobarbital or pentobarbital or some similar drug. I myself am reluctant to use any further medications than those I have mentioned, but there are always exceptions.

As far as I know the only usefulness of alcohol is, if in small and nondisturbing doses, it creates a beneficial mild euphoria. Alcohol does not seem to me to have any important place in pneumonia therapy.

I mention diathermy and pulmonary collapse therapy merely to confess inadequate experience with these and similar procedures and to give my impression that at this time they do not seem to occupy a place in the management of pneumonia.

Time does not permit a discussion of the various complications and sequelae of pneumonia. Furthermore until further experience and data have been gained with the newer and more effective therapeutic agents, serums and chemicals, alone or in combination, physi-

cians are in no position to discuss the management of these conditions intelligently.

The general treatment of the pneumonia patient as I have outlined it seems highly innocuous in contrast to the era in which bleeding, purging and puking were almost routine. Likewise physicians have given up cupping, counterirritation and poultices. They no longer subject their patients (and the nurses) to the icy blasts of winter. However there may be merit in the air conditioned room in summer and perhaps in a room where the temperature can be controlled.

Even if slush baths are not used for reduction of temperature, certain forms of bathing which have a sedative effect are regarded highly. That and the judicious employment of rubbing or of massage are accepted as a part of good nursing care.

In effect, an attempt is made to manage the patient so as to conserve his strength, so that he may be fortified against the devastating tumult of the battle within him and that he may contribute what he can to the suppression of the enemy pneumonia. Pneumonia is always to be regarded as one of the doctor's most common major emergencies. Loss of time may mean loss of life. During the few days of emergency, no detail is trifling. And while the glory of a victorious battle will go to the big guns of chemotherapy, serum therapy and oxygen therapy, this battle, like other battles, is often actually won by the nonspectacular infantry; in this case, the general care of the patient.

Special Article

REPORT OF THE AMERICAN COMMITTEE ON OPTICS AND VISUAL PHYSIOLOGY

WALTER B. LANCASTER, M.D., CHAIRMAN
BOSTON

The committee has held some half dozen meetings since the last report and has carried on an extensive correspondence. In fact, the clerical work entailed has become too large a burden to be carried by our too willing secretary, Dr. Conrad Berens. The committee therefore voted to request the parent societies to make provision for office expenses by each contributing say \$50 to be used for this purpose.

The work of this committee is largely divided among subcommittees, whose reports form the basis of discussion and action by the whole committee. These subcommittees will be taken up seriatim:

I. COMMITTEE ON MOTOR ANOMALIES AND ORTHOPTIC TRAINING

DR. CONRAD BERENS, NEW YORK, CHAIRMAN

The National Orthoptic Council has begun its work; the first examination was held in New York on March 30 and April 1 and ten candidates were examined.

II. COMMITTEE ON CODE OF LIGHTING

DR. ALFRED COWAN, PHILADELPHIA, CHAIRMAN

There is no new business.

During the past year a related series of experiments, which were approved in principle by the committee, has been carried out on the effects of reading at 1 and 50

footcandles on the total metabolism and pulse rate at the Harvard Fatigue Laboratory by McFarland, Knehr and Berens. Negative results were obtained in this study. The data are of significance in correcting certain impressions that reading under different levels of illumination gives rise to marked alterations in metabolism.

From these data it seems justifiable to conclude that the recommendations concerning illumination in schools made by the Committee of Illuminating Engineers in 1938 should be used as a guide if new construction is undertaken or improvements are to be made in some existing school rooms; but until the results of further researches are available, it might be unwise to make drastic changes in the present lighting arrangement in all the schools because the proposed changes would increase the tax burden and possibly would be unwarranted. Another important possibility is that the recommended standards are too low, especially for the visually handicapped children in the regular class room.

III. COMMITTEE ON NEW INSTRUMENTS

DR. SANFORD R. GIFFORD, CHICAGO, CHAIRMAN

A final report was made on the telebinocular for examining and sifting out school children in need of expert attention for their eyes. The decision was reached that this instrument was not well suited for this purpose and its use was condemned.

At the request of the committee, a method has been worked out in Boston which the committee wishes to have tried out in other places where cooperation with competent ophthalmologists can be secured. It is the purpose of the committee not to recommend any method until it has been subjected to the crucial test of applying it in several independent localities to groups of say fifty to 100 children, every one of whom is given a thorough examination under cycloplegia by an ophthalmologist to check the results obtained by the school nurse or the teacher who uses the test under ordinary working conditions. It was on the basis of such check tests that the telebinocular was rejected.

IV. COMMITTEE ON OPTOMETRY

DR. S. JUDD BEACH, PORTLAND, MAINE, CHAIRMAN

The many difficult problems involved in the relations between ophthalmologists, optometrists and the public were earnestly discussed from many angles. An immediate solution is not to be hoped for. Only by gradual education and evolution can the goal of cooperation desired by many be attained. The committee voted to request the Section on Ophthalmology of the American Medical Association to reconsider the vote taken in 1935 at a special executive session without previous notice and without discussion. This action in 1935 declared it to be "unethical for members of the American Medical Association to give lectures or courses of instruction to or consult with any one not associated with the actual medical service."

V. COMMITTEE ON BETTER LIGHT—BETTER SIGHT

DR. WILLIAM L. BENEDICT, ROCHESTER, MINN., CHAIRMAN

No report was made.

VI. COMMITTEE ON RELATIONSHIP BETWEEN OPHTHALMOLOGISTS AND OPTICIANS

DR. SANFORD R. GIFFORD, CHICAGO, CHAIRMAN

Dr. Gifford sent out a questionnaire and secured valuable information, especially as to the matter of rebates, retail prices, and so on. He also had confer-

ences with some of the leading manufacturers, whom he found very anxious to remedy existing defects.

As an entering wedge in attacking the present system, he proposed, and the committee endorsed, a plan suggested by Alan Woods as follows: "In communities where there are no straight retail dispensers of optical goods (other than optometrists) physicians who do not desire to participate in any way themselves in the retail dispensing of glasses may refer their patients directly to the wholesale houses who ordinarily act as oculists' agents in the dispensing of glasses. On such reference, the wholesale houses will furnish to patients, on specific prescriptions of such physicians, glasses of comparable quality, including protected lines, at the minimum retail price prevailing in the community and will assume responsibility for breakage, adjustments, collections, etc., such as are ordinarily assumed by their accounts.

"On other than protected lines the foregoing proposal should effect a saving averaging 20 per cent or slightly more on a combination of lenses and frames as compared with the retail price commonly employed. The results will necessarily vary according to local conditions, but the general results will be as stated."

VII. COMMITTEE ON GRADING LENSES

DR. ALFRED COWAN, PHILADELPHIA, CHAIRMAN

A definition was presented of a first grade lens which was adopted, with slight modification by the committee, as follows:

A first class lens is one which, when finished, has the proper focal power and correct direction of the axis of the cylinder; is properly transparent; has regularly smooth, polished surfaces; contains no flaws, scratches or other blemishes, and is accurately centered with regard to the visual lines. Regardless of the price, any lens which meets with these requirements must be considered first class.

Ophthalmologists, of course, cannot be expected to, nor can any one else, tell whether the lens which meets these requirements was originally labeled first, second or third class.

SPECIFICATIONS FOR ILLUMINATED EYE CHART AND FIXATION LAMP UNIT

Dr. Benedict presented specifications for illuminated eye chart and fixation lamp unit, prepared by the Advisory Committee of Ophthalmologists to the Eye Health Committee of the American Student Health Association in cooperation with the National Society for the Prevention of Blindness.

The members of this advisory committee are Drs. Benedict, Gradle and LeGrand Hardy; they were aided by W. F. Little, consulting engineer.

These specifications were accepted by the committee.

COMMITTEE ON POLAROID

DR. W. H. LUEDDE, ST. LOUIS, CHAIRMAN

The facts presented in the report of our committee were not challenged by our conferences last October with Mr. Land, the originator of the Polaroid crystal layer, but the committee was pleased, at the suggestion of Dr. Lancaster, to reconsider its conclusions.

It is true that a large measure of the beneficial effect of the Sun or Daylight glasses is the result of the olive green tint added to the polaroid in these glasses, but clinical tests appear to show the superiority of glasses made with the layer of polaroid substance.

A United States Forest ranger and official snow observer in the highest Rocky Mountain region

throughout the winter gave assurance and so did others that the polaroid glasses were notably superior to the large variety of simple tinted lenses they had previously used. If funds were available, adequate clinical tests of a larger number of persons under different conditions might be considered.

It might be recommended that the name of Polaroid Daylight glasses be changed frankly to "tinted" Polaroid Sunglass instead of making the explanation in fine print where it may pass unnoticed. The practical elimination of the most annoying reflected light, which is largely polarized, is so advantageous in the outdoor use of glasses to protect against glare that proper "tinted" Polaroid glasses must be acknowledged to be much more efficient than mere tinted lenses.

Theoretically, the proper use of the polaroid film should be a great advantage in night driving to eliminate the dangers incident to glare of headlights and windshields. It is hardly possible that the expense of this equipment could be considered exorbitant when weighed in relation to the saving of human lives.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

PESCOR SHORTWAVATHERM RX MODEL NOT ACCEPTABLE

Manufacturer: Physicians Electric Service Corporation, 1054-1056 West Sixth Street, Los Angeles.

In the interest of public protection the Council has recently given attention to the Pescor Shortwavatherm, RX Model. It appears from a letter addressed to dealers that the device is sold directly to the public: to quote, "The low list price of \$145 includes heavy sponge rubber molded pads and cords, etc., and should make possible volume from a new 'customer-channel', the surface of which hasn't even been scratched," and "... a Short Wave Diathermy specially designed for patient's use at home ..." and, "Patients usually rent Short Wave Diathermia for home use to facilitate treatments, expense and departures from business."

The unit is portable, and accessories include rubber encased cords and two 6 by 8 inch rubber pads. Sinus pad, orificial and cuff electrodes are also available. The unit is designed to operate at from 50 to 60 cycles, 115 to 125 volts alternating current. It utilizes two vacuum tubes. The manufacturer claims an output for the device of from 200 to 250 watts and a wavelength of 16 meters. A surgical current is also provided for which a foot switch and cutting knives are available.

The advertising sheet "Pescor Shortwavatherm RX Model" in the opinion of the Council contains several objectionable features. Diathermy is recommended for a wide variety of ailments, which are so generalized in nature as to suggest that it is a general panacea for almost any ill. For instance, it is advocated for cardiac ailments (selected), constipation, gallbladder diseases, spleen, gastric ailments, goiter (selected), hay fever, intestinal neurosis, spinal cord ailments, pelvic diseases, pancreas ailments, liver diseases and head colds. Other questionable statements are "Penetrability beyond requirements," "Abundant power," and "Simple as A. B. C." The claim is advanced that applications may be made by any one, which might lead to unfortunate consequences for uninformed persons who attempt self treatment. The firm also states that the unit possesses a "Penetrability Meter." No critical evidence has been presented to the Council to substantiate the value of such a meter.

Another circular addressed to "Dear Doctor" points out that the appliance is "... especially designed for your patients' use at home, or as an auxiliary machine for your office ..."

It also recommends the device for minor surgery, as do the other pieces of advertising. An apparatus which is sold both to the public and to the physician, as this appears to be, for both medical diathermy and minor surgery, can only be, the Council believes, (1) a dangerous appliance for the layman to use or (2) an ineffective apparatus for the treatment of disease.

In the opinion of the Council on Physical Therapy, the Physicians Electric Service Corporation appears to be promoting an instrument in a way that is detrimental to the public interest and rational therapeutics. Sales methods which promote self treatment of disease by those unqualified to practice medicine, and appeal to the public with unscientific persuasions, may harmfully enhance a feeling of false security on the part of the public. In the light of the foregoing report, the Council on Physical Therapy voted not to accept the Pescor Shortwavatherm RX Model for inclusion on the Council's list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

SOLUTION QUININE AND UREA HYDROCHLORIDE, 5% WITH PROCAINE HYDROCHLORIDE 2%, 30 CC.

VIALS (UPJOHN) NOT
ACCEPTABLE FOR

N. N. R.

When the Upjohn Company presented this preparation for the Council's consideration its attention was called to the fact that the Council had not accepted any sclerosing or obliterative agents for the treatment of hemorrhoids although it has accepted sclerosing agents in the treatment of varicose veins. The firm was asked to supply any evidence it might have to warrant the Council in accepting a 5 per cent solution of quinine and urea hydrochloride with procaine hydrochloride for such use. In reply the firm submitted excerpts from current literature and textbooks on this subject.

The Council's referee examined the submitted material and reported his feeling that no question should be raised as to the correctness of the excerpts. He pointed out that some who report successful use of this procedure have had wide experience in this condition, while others of the authors quoted probably have not been especially interested in this subject but have written the quoted material as part of the larger question of surgery. The referee feels that there is no objection to the occasional use of this method by men who have had wide experience. He pointed out, however, that acceptance of a product for New and Nonofficial Remedies with recommendation for use in this procedure would involve its use by men who may not be especially well trained in recognition of many of the conditions which simulate or are associated with hemorrhoids. The referee further pointed out that accidents and unfavorable results which follow from this method of treatment are rarely reported, although it is well known that such have frequently occurred. The Council agreed with the referee that it would be unwise to place the weight of the Council's opinion in favor of general use of the injection treatment of hemorrhoids.

The excerpts from the literature submitted by the firm were sent to a consultant who probably has had as wide an experience in the treatment of hemorrhoids and similar rectal conditions as any one in the country. This consultant reported as follows:

The material submitted by the firm fails to point out the dangers involved when the injection treatment of hemorrhoids is undertaken without expert knowledge of the various lesions that occur in the rectum, and of the various complications such as hemorrhage, ulceration and stricture of the rectum as well as deposition of inert oily substances in the submucosa of the bowel, which results in chronic inflammatory foreign bodies. Used by men specially trained in this work, under definite indications, the injection treatment of internal hemorrhoids may be safely done as a

palliative procedure. It is my opinion that it is a rare thing to expect permanent cure, because if well developed internal hemorrhoids are present almost always there are also present varicose veins beneath the skin as external hemorrhoids which cannot be treated by injection and which subsequently cause dilatation of the veins, making internal hemorrhoids.

The referee is aware of the fact that many drugs, such as insulin or digitalis, may result in fatal accidents if improperly used. There are, however, several methods of treating hemorrhoids. It is known that the injection method is subject to accidents—infection, embolism, and so on. It is likewise true that in the hands of some men this method can be used successfully in selected cases. By accepting the recommendations for the use of injection treatment of hemorrhoids, the Council would add the weight of its influence in favor of routine or general use of this method in unselected cases, which will include those in which the outcome will not be favorable. By refusing recognition to such claims, the Council denies no one the right to use sclerosing agents for hemorrhoids if he wishes to do so. They are already available and are in New and Nonofficial Remedies but not with specific recommendations for such use. The Council has repeatedly allowed some claims and denied others for many drugs, and has consistently refused to accept any drug for use in the injection treatment of hemorrhoids.

In view of the foregoing the Council voted that for the present it continue its policy that no preparation for the injection treatment of hemorrhoids be accepted for New and Nonofficial Remedies and declared Solution Quinine and Urea Hydrochloride, 5% with Procaine Hydrochloride 2%, 30 cc. vials-Upjohn unacceptable for inclusion in New and Nonofficial Remedies, since it is recommended for this purpose.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

ADRENALIN (See New and Nonofficial Remedies, 1939, p. 229).

The following dosage form has been accepted:

Amoules Adrenalin in Oil, 1 cc.: A vegetable oil (peanut oil) suspension of adrenalin base, each cubic centimeter of the suspension representing 2 mg. of adrenalin.

ASCORBIC ACID (See New and Nonofficial Remedies, 1939, p. 499).

Tablets Ascorbic Acid, 25 mg.

Prepared by Smith-Dorsey Co., Inc., Lincoln, Neb.

Cevitamic Acid-Abbott (See New and Nonofficial Remedies, 1939, p. 500).

The following dosage form has been accepted:

Tablets Cevitamic Acid-Abbott, 0.05 Gm.

NICOTINIC ACID (See New and Nonofficial Remedies, 1939, p. 495).

Tablets Nicotinic Acid, 50 mg.

Prepared by Smith-Dorsey Co., Inc., Lincoln, Neb.

STEARNS HALIBUT LIVER OIL WITH VIOSTEROL (A. R. P. I. PROCESS).—A brand of halibut liver oil with viosterol-N. N. R.

Prepared by the International Vitamin Corporation, New York. The viosterol (A. R. P. I. Process) is manufactured by the American Research Products, Inc., a division of General Mills, Inc., Minneapolis, under license agreement with E. J. du Pont de Nemours Company (Frederick Stearns & Company, distributor). U. S. patent 2,117,100 (May 10, 1938; expires 1955).

Stearns Halibut Liver Oil with Viosterol (A. R. P. I. Process) (with other fish liver oils) Capsules.—Each capsule contains 8,500 units (U. S. P.) of vitamin A and 1,700 units (U. S. P.) of vitamin D.

Stearns halibut liver oil with viosterol (A. R. P. I. Process) is prepared by combining refined halibut liver oil, one or more other fish liver oils, and viosterol (A. R. P. I. process) in such proportions as to bring the vitamin potency of the finished product to 10,000 units (U. S. P.) of vitamin D and 65,000 units (U. S. P.) of vitamin A per gram. Viosterol (A. R. P. I. Process) is ergosterol activated by low velocity electrons.

SATURDAY, OCTOBER 7, 1939

PERIODICITY OF INFLUENZA

Like other epidemic diseases, influenza tends to fluctuate in its frequency and in its virulence. Furthermore, this intermittence was evident not only in the case of the great pandemics, such as the one of 1917-1918, but also in the minor epidemics which occurred both before and after that calamity. It has been difficult however to relate the fluctuations which actually occurred with any definite time or seasonal factor. When the literature on influenza was reviewed by Jordan¹ in 1927 the theory of Brownlee, who attempted to relate endemic "influenza" to a periodicity of thirty-three weeks, was dominant. Jordan pointed out, however, that the evidence available was not sufficient to establish definitely the conclusion that a nonseasonal cycle as predicted by Brownlee was an inherent and general characteristic of influenza in postpandemic periods, because the observations did not cover a sufficient number of different areas to give them generality, because they failed to cover a sufficient period of time in the life history of influenza and because for the years 1918-1923 the facts adduced, although apparently consistent with the hypothesis of a thirty-three week cycle, seemed to be also consistent with the simpler assumption of a cycle approximating twelve months.

Equally speculative has been the explanation for the irregular intervals existing between the great pandemics. The various explanations that have been advanced, according to Jordan, fall into two main categories: those postulating a change in the distribution or nature of the virus, and those attributing the phenomenon to something in the condition of those attacked. To these a third may be added; namely, a decrease of the opportunities for spread of the infection. After consideration of the evidence up to 1927, the most plausible of these hypotheses, he thought, rested in a change in the virulence of the infecting microbe as the essential cause of the rise and fall of pandemic influenza. The coming

into existence of a peculiar strain of influenza virus to cause the pandemic manifestations has not been wholly disproved by any subsequent studies and has, in fact, received some theoretical support by demonstration of different strains of influenza virus both in man and in certain lower animals.

During the last twelve years much further study has been accorded this subject, although no pandemic has appeared. Recently Webster² has again challenged Brownlee's thirty-three week single phase cyclic hypothesis and has presented a two phase theory which he thinks may explain the observed periodicity of influenza. While not denying the part played by seasonal influences in influenza mortality, the twelve month cycle, Webster says, does not permit of predictions with any accuracy nor can it account for the major epidemics in the summer and autumn. From his analysis of the past forty-nine years (1890-1939) he postulates a diphasal activity of influenza most strikingly evident in the three pandemic waves of 1918-1919. This represents a modification of Brownlee's single phase thirty-three week theory with a seasonal factor and accounts, Webster believes, for all the main phenomena. Phase 1, that occurring at approximately the thirty-third week interval, has been the major phase, although phase 2 (the intermediate) about sixteen weeks after phase 1 has led to a number of serious outbreaks (as in February-March 1924 and January-March 1932, he says, and to the first and third pandemic waves of 1918-1919). Some variation of the thirty-third week period is occasionally evident and indeed at present the evidence suggests that a thirty-six week period exists now. The cause of variation of the interval, Webster believes, may be one intrinsic to the virus or be due in part to a seasonal element. The well known seasonal incidence of interpandemic influenza may be due not only to meteorologic conditions and to a lowered resistance of the population in the winter-spring months but to an intrinsic increase in activity on the part of the virus.

The factual data on which this theory is based are restricted. Adequate testing of the theory should include more complete analysis of morbidity rates and the study of minor outbreaks and of relapses and recurrences. On this theory, however, it should be possible to predict to some degree future epidemics and outbreaks. The most likely time for a major epidemic would be, he says, February 1941 (phase 1 outbreak), although a phase 2 outbreak of some severity seems possible in February 1940.

Critical analysis of this interesting theory does not as yet lead, however, to complete conviction. In a previous study Webster attempted to demonstrate the periodicity of cancer and other neoplastic diseases, which

1. Jordan, E. O.: Epidemic Influenza, Chicago, American Medical Association, 1927.

2. Webster, J. H. D.: The Periodicity of Influenza, Edinburgh M. J. 46: 591 (Sept.) 1939.

he says is closely similar to that demonstrated for influenza. This is a most surprising concordance, since there seems little else of parallelism in these two diseases. Furthermore the cycle of thirty-three weeks of Brownlee's hypothesis, which in the main Webster accepts, has not yet been freed from all the criticisms previously made by Jordan and others. Webster also states that in this cycle missed periods are often seen, especially in the summer and autumn months, and the half-periods (phase 2), which Webster suggests are due to a double strain or grouping of infected strains, cannot as yet be accepted as a wholly established phenomenon. No matter how this hypothesis withstands further critical analysis, its usefulness as an instrument of prophecy will receive practical trial in connection with the predicted outbreaks of February 1940 or February 1941.

THE RENAISSANCE OF SILK IN SURGERY

Clinical experience has demonstrated that the problem of ideal wound healing is complicated. It involves not only the presence or absence of bacteria in the wound, the nature of the organisms and the resistance of the patient but also a number of other factors. Aseptic healing of an incision requires a systematic, meticulous, aseptic operating room technic in all its many details, minimum traumatization of the tissues, complete hemostasis and, less important, but nevertheless significant, the selection of proper ligature and suture material. After more than half a century of use of an absorbable suture, many surgeons now seem ready to discard such materials to return to the use of silk in the repair of clean wounds and incisions. The older masters of the craft who, after unsatisfactory experience, rejected catgut and returned to silk include such leaders as Theodore Kocher, Heidenhain, Hagler and, in our own country, William Stewart Halsted.

In a now oft quoted paper, published in *THE JOURNAL* in 1913, Halsted¹ thus summarized his objections to the use of catgut:

The relatively high cost of catgut, its bulkiness, the inconveniences attending its use and sterilization, its inadequacy, the uncertainty as to the time required for its absorption, and the reaction which it excites in a wound, induced me to discard it completely for clean wounds in the surgery both of the human subject and of animals. With the fine silk in our wounds, which for twenty-three years have, as a rule, been closed without drainage, suppuration almost never occurs. But catgut, even that which we have no cause to believe is not sterile, irritates the wound for some reason, perhaps because it serves as culture medium for saprophytic organisms which are carried into it from the deep epithelium and follicles of the skin. It should be borne in mind that during the greater part of the period of its disintegration the catgut suture is not only not serving its purpose but is playing the role of necrotic tissue, of a culture

medium. It is well within reason to expect that the technic may be at least so perfect when silk is employed that the wound will become infected not once in a hundred cases.

Recent clinical and experimental studies seem to bear out Halsted's position. Thus, Shambaugh and Dunphy² demonstrated in dogs that operative wounds repaired with silk tolerate bacterial contamination better than similar wounds repaired with catgut; that the healing of experimental suppurating wounds is not appreciably delayed by the presence of buried silk sutures and ligatures, provided a fine grade of silk is used, the sutures are cut close to the knot, and continuous sutures are not employed. They also showed that experimental suppurating wounds repaired with fine silk may heal completely without the removal or the spontaneous discharge of the silk sutures. Jenkins,³ in his analysis of 1,294 cases of abdominal wound disruption, mentions among the causes imperfections in the catgut and rapid digestion as a result of sensitivity to catgut protein, to chromic acid and to infection. Kraissl⁴ demonstrated the possibility of an allergic reaction to catgut in patients with edema of the wound edges and disruption of abdominal wounds. He was able to sensitize guinea pigs to plain and to chromic catgut and to chromic acid with the result that 30 per cent of these animals disrupted the abdominal wound following a celiotomy. All of a series of twenty-six control guinea pigs healed normally except one. It appears likely therefore that the local reaction in patients allergic to catgut predisposes to infection and favors wound disruption. The incidence of this allergy, according to Kraissl, increases with a history of allergy or of a previous operation.

Superiority of silk over catgut, according to Meleney,⁵ is due to the following facts: 1. Hemostasis is better, for the silk knots do not become untied as do catgut knots. 2. The cellular and fluid reaction about silk is minimal while about the catgut it is maximal; silk is almost inert in the tissues, while catgut is dead tissue which must be digested. 3. The use of silk automatically requires the surgeon to be more gentle with the tissues.

Whipple⁶ stated at a conference last year that, since silk has been adopted in his clinic, the improvement in wound healing has been so striking as to leave no room for argument as to both immediate and late results. He emphasizes that one should not attempt to use silk unless one is willing to change one's technic and instruments. The essentials of this technic include the use of the finest grades of silk, interrupted sutures, careful hemostasis and a constant effort to tie sutures without tissue tension.

MAGNESIUM IN NUTRITION

In recent years numerous quantitative studies have greatly enhanced our understanding of the influence of mineral elements in animal economy. The belief that magnesium is essential for growth in the higher plants was confirmed in 1906, when Willstätter discovered that it forms an integral part of the chlorophyll molecule. Until 1932, however, when Kruse and his co-workers¹ published their observations on magnesium deficiency in the rat, the indispensability of this element for the animal organism had not been clearly established.

The extent to which a deficiency of magnesium may occur in the human dietary is not definitely known. Furthermore, the nature of the pathologic changes that might be expected to occur as a result of a deficiency of magnesium has only of late been disclosed by experimental studies on animals. Duckworth² has recently presented the symptomatology of experimental magnesium deficiency. The fragmentary evidence available indicates that one effect of magnesium deficiency is a disturbance of normal calcium metabolism. Extensive pathologic depositions of calcium salts in the yellow elastic fibers of the endocardium and in the aorta, the jugular and the larger arteries as well as in the soft tissues have been described in calves whose regimen was low in magnesium. Similarly, in rats which received an inadequate amount of magnesium in the diet an increase in the percentage of calcium in the heart, kidney and muscles has been observed. The manifold effect of magnesium deprivation was shown by Kruse,¹ who found that magnesium deficiency in rats was characterized by vasodilatation, hyperemia of the cutaneous vascular system, increased hyperirritability, cardiac arrhythmia and fatal tonic-clonic spasms. Similar effects have been observed in dogs on a magnesium-poor diet. Determinations of the magnesium content of the serum of dogs on such rations have shown that there is an early and progressive decrease in the amount of the metal present and that the value remains low during the convulsive period. New problems regarding the causation of tetany have arisen as a consequence of its occurrence in animals suffering from magnesium deficiency.

The human requirement for magnesium has been studied by a number of investigators. On the basis of balance experiments, the daily magnesium requirement of children from 4 to 7 years of age has been estimated to be not less than 13 mg. per kilogram of body weight. In a group of preschool children investigated by Daniels and Everson,³ 75 per cent were found to be receiving less than the optimal amount of this element as judged by retention of magnesium under certain conditions. The meager information that is available regarding the magnesium requirement of pregnant women indicates that from 350 to 450 mg. daily is necessary during preg-

nancy. The daily magnesium requirement for the maintenance of adults has been reported to be as low as 0.2 Gm. and as high as 0.6 Gm. Duckworth assumes that the lower estimate is more nearly correct. Judging from data available on the magnesium content of freely chosen American diets, the requirement will be met provided the daily energy intake is in the vicinity of 2,500 calories. The possibility of adult human deficiency cannot be ruled out, however, until further information is available concerning the magnesium requirement.

Hirschfelder⁴ has suggested that the clinical occurrence of magnesium deficiency under certain conditions is within the realm of possibility. This investigator observed low levels of magnesium in the plasma in several patients accompanied by hyperirritability of the neuromuscular system often associated with muscular twitchings and convulsions. Nevertheless, so little is known of the function of magnesium in the organism that clinically observable abnormalities in man cannot at present be said with certainty to be due to magnesium deficiency or to a disorder of magnesium metabolism. The systematic study of magnesium metabolism by accurate analytic and experimental methods is little more than begun. Future investigations may be expected to add considerably to our knowledge of this problem.

Current Comment

OXYGEN AND CARBON DIOXIDE IN PNEUMONIA

Although oxygen has been employed in pneumonia for nearly two decades, not all of the factors concerned in its administration have been thoroughly elucidated. In an experimental investigation of this subject by Cohn and his collaborators,¹ five series of experiments were performed on carefully picked dogs, embodying the determination of the normal physiologic variations in oxygenation and acid-base balance occurring in the blood of the dogs, the determination of the effect of experimental pneumonia on the oxygenation and acid-base balance of the blood, the determination of the effect of breathing air enriched with oxygen alone on normal dogs and on anoxemic dogs, the determination of the effect of the breathing of air to which carbon dioxide had been added on normal and pneumonic dogs, and the determination of the effect of breathing air enriched with both oxygen and carbon dioxide on normal and pneumonic dogs. Careful controls were employed in all experiments. The experimental bronchopneumonia was produced by the intrabronchial injection of 1 per cent hydrochloric acid. Although the pneumonia was accompanied by pronounced anoxemia, significant change in the acid base balance of the arterial blood was not observed. The investigators also found that oxygen-enriched atmosphere increased the oxygen saturation of

4. Hirschfelder, A. D.: *Clinical Manifestations of High and Low Plasma Magnesium*, *J. A. M. A.* **102**: 1138 (April 7) 1934.

1. Cohn, D. J.; Tannenbaum, Albert; Thalheimer, William, and Hastings, A. B.: *Influence of Oxygen and Carbon Dioxide on the Blood of Normal and Pneumonic Dogs*, *J. Biol. Chem.* **128**: 109 (April) 1939.

the arterial blood of normal dogs slightly and of pneumonic dogs greatly, without alteration in the acid-base balance. Addition of carbon dioxide to the inspired air caused a slight increase in the arterial saturation of both normal and pneumonic dogs. The addition of carbon dioxide to the inspired air was accompanied by a change in the acid-base balance of the blood indicative, they believe, of respiratory acidosis. This acidosis was more severe in pneumonic than in normal dogs. Moreover, oxygen-enriched atmosphere containing carbon dioxide was accompanied both by increased oxygenation of the blood of the normal and pneumonic dogs and by respiratory acidosis, which was greater in the pneumonic than in the normal dogs. Both normal and pneumonic animals kept in high carbon dioxide atmosphere showed a change in acid-base balance indicative of physiologic compensation. The evidence available indicates, the investigators believe, the decreased ability of pneumonic dogs to eliminate carbon dioxide. Since oxygen alone achieves the desired reoxygenation of the blood when this is possible, the addition of carbon dioxide is, they believe, of doubtful benefit. Furthermore, the usual rapid respirations induced by carbon dioxide represent an added burden to an already overburdened respiratory and cardiovascular system. In view of the conflicting clinical evidence on the value of adding carbon dioxide to oxygen in the treatment of pneumonia, these clear-cut experimental studies can be adduced as offering evidence that the use of oxygen inhalations alone may be indicated in the treatment of pneumonia.

Association News

ANNUAL CONFERENCE OF SECRETARIES OF STATE ASSOCIATIONS AND EDITORS OF STATE JOURNALS

The Annual Conference of Secretaries of Constituent State Medical Associations and Editors of State Medical Journals will be held in Chicago November 17 and 18. The first session will be convened at 10 a. m. Friday, November 17. All meetings will be held in the Assembly Room of the American Medical Association Building, 535 North Dearborn Street, Chicago.

Officers of state medical associations and county medical societies who wish to attend this conference will be heartily welcome, as will individual members of the Association who may desire to be present.

ADDRESSES BY OFFICIAL STAFF

DR. PAUL C. BARTON:

- October 11—Dubuque County Interprofessional Society, Dubuque, Iowa.
- October 20—North Shore Alumnae of Chi Omega, Evanston, Ill.

DR. W. W. BAUER:

- October 12—Fifth District, Federation of Women's Clubs, Lamoni, Iowa.
- October 15-19—American Public Health Association, Pittsburgh.
- October 25-26—Parent Teacher Association, High Schools, Nashville, Tenn.
- October 27-28—Eastern Tennessee Education Association, Knoxville, Tenn.

DR. MORRIS FISHBEIN:

- October 10—Town Hall, Grand Junction, Colo.
- October 12—Associated Town Halls, Inc., Jefferson City, Mo.
- October 13—Northwest Division of Iowa State Teachers Association, Sioux City, Iowa.
- October 26—Bethany College, Bethany, W. Va.
- October 27—Eastern Ohio Teachers Association, Cambridge, Ohio.

DR. ROCK SLESTER:

- October 11—Delaware State Medical Society, Wilmington, Del.
- October 18—Jackson County Health Forum, Kansas City, Mo.
- October 30—Oklahoma City Clinical Society, Oklahoma City.

DR. PAUL A. TESCHNER:

- October 16—University Clinics' Nurses Class, Chicago.
- October 26—Annual Meeting, Wisconsin Anti-Tuberculosis Association, Milwaukee.

DR. NATHAN B. VAN ETEN:

- October 9—The Columbia Medical Society, Columbia, S. C.
- October 11—Indiana State Medical Association, Fort Wayne.
- November 1—The Interstate Post Graduate Medical Association of North America, Chicago.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal.—Dr. William E. Bones, Montgomery, associate in child hygiene, state department of health, has been appointed to the staff of the Council on Medical Education and Hospitals of the American Medical Association, Chicago. He graduated at Vanderbilt University School of Medicine, Nashville, Tenn., in 1931.

Changes in Health Officers.—Dr. George E. Maddison, Monroeville, formerly health officer of Monroe County, has been appointed health officer of Henry County, succeeding Dr. Carl T. Martin, Abbeville, who resigned to enter private practice. Dr. William A. Dodson Jr., Fayette, has been named health officer of Winston County, succeeding Dr. Paul H. Hilbert, Double Springs, who has joined the health department in Cincinnati, it is reported.

Special Society Elections.—Dr. Charles N. Carraway, Birmingham, was elected president of the Alabama Association of Railroad and Industrial Surgeons September 12 at its meeting in Birmingham; Dr. Napoleon S. Johnson, Clanton, vice president, and Dr. Jacob U. Ray, Woodstock, secretary for the twenty-third consecutive year.—The Alabama State Pediatric Society reelected its officers at the recent annual session in Birmingham: Drs. Stewart H. Welch, Birmingham, president; M. Vaun Adams, Mobile, vice president, and William R. Britton, Montgomery, secretary-treasurer. The next annual meeting will be in Birmingham, the time to be determined later.

ARKANSAS

Changes in Medical School Staff.—Recent changes include the appointment of Dr. Charles R. Henry as professor of obstetrics and gynecology and of Forrest R. Davison, Ph.D., assistant professor of pharmacology, University of Vermont College of Medicine, Burlington, as assistant professor of physiology and pharmacology. Dr. Edgar J. Poth, assistant professor of surgery, Stanford University School of Medicine, San Francisco, has been appointed head of the department of surgery.

District Meeting.—The Fifth Councilor District Medical Society was addressed in Camden October 5 by Drs. William Hibbitts, Texarkana, Texas, on "A Brief Review of Intestinal Obstruction"; Dorman B. Barber, Alexandria, La., "Latent Scurvy," and Charles W. Mayo, Rochester, Minn., "Surgery of the Right Colon." A public session was addressed, among others, by Mayor Don Harrell, Camden; Dr. Leopold H. Reeves, Fort Worth, Texas, "The Implications of Socialized Medicine"; Dr. Mayo, "Time and Its Relation to Disease," and Governor Carl Bailey.

CALIFORNIA

Society News.—The Los Angeles Society of Ophthalmology and Otolaryngology was addressed September 25 among others by Dr. Victor Goodhill on "The Histopathology of Syphilis of the Ear."—At a meeting of the Los Angeles Society of Neurology and Psychiatry September 20 the speakers were Drs. Archie M. Roberts on "Psychiatry in Internal Medicine" and Jesse L. Henderson, Compton, "Psychotherapy," and Thomas D. Cutsforth, Ph.D., "Personality Problems of the Alcoholic."

Study of Methods for Preserving Blood.—The Rosenberg Foundation has given \$6,000 to the University of California to establish a blood bank at the San Francisco Hospital. The grant, which will be administered by an advisory committee composed of the deans of the medical schools of California and Stanford universities and the director of health of San Francisco, will be used to stimulate investigation of methods for preserving blood in centralized pools or banks and for distributing it in good condition. The grant stipulates that the work is to be done by the University of California; Miss Cordula Hull, assistant in medicine at the university, has been named to carry on the research.

DELAWARE

State Medical Meeting in Wilmington.—The Medical Society of Delaware will hold its annual session at the Delaware Academy of Medicine, Wilmington, October 9, under the presidency of Dr. Meredith I. Samuel, Wilmington. The society is celebrating its sesquicentennial this year. The speakers on the program will include:

- Dr. Eli K. Marshall Jr., Baltimore, Sulfapyridine as a Bacterial Chemotherapeutic Agent.
- Dr. John H. Foulger, Wilmington, subject not announced.
- Dr. John T. Bauer, Philadelphia, The Difficulty in Early Diagnosis of Primary Cancer of the Lung.
- Dr. William Edwin Bird, Wilmington, Right Paraduodenal Hernia.
- Dr. Fred H. Albee, New York, Massive Resection of Bone Sarcoma with Immediate Bone Graft Replacement.
- Dr. Charles William Dunn, Philadelphia, Hormone Therapy: Uses and Abuses.
- Dr. George Howard Cross, Chester, Pa., Ophthalmology and Its Relation to Industry.

The sesquicentennial of the state society will be held in a building which dates nearly as far back as the society itself. The old Delaware Bank Building, now the Delaware Academy of Medicine, was chartered in 1795 and the present building was erected in 1816 at Sixth and Market streets, where it stood until 1931, when it was removed to its present location along the Park Drive on land adjacent to that once held by Tyman Stidham, the first doctor in Delaware. The building was reerected as it stood originally with the exception of a few modern interior alterations. The original hand-hewn rafters joined with wooden pegs, the staircase and floors have been preserved, as well as the original fence surrounding the building; all are as they appeared one hundred and twenty-three years ago. A feature of the sesquicentennial is a historical exhibit to help picture the medical background of the state. The display includes photographs of presidents of the society, old books, instruments, diplomas, fee bills and many other items of special interest. The women's auxiliary to the state medical society will meet October 10.

FLORIDA

Society News.—Drs. Edward W. Cullipher and Leonidas W. Dowlen addressed the Dade County Medical Society, Miami, recently on "Common Foot Ailments" and "Endocrinology of Menstruation" respectively.—Dr. Michael Smith, West Palm Beach, addressed the Palm Beach County Medical Society recently on "The Modern Conception of Tuberculosis."

District Meeting.—The third annual meeting of the South-west Medical District Society was held at Lakeland September 28 at the Yacht and Country Club under the presidency of Dr. Herman W. Watson. Dr. John F. Wilson, president of the Polk County Medical Society, gave the address of welcome. The speakers included Drs. George F. Highsmith, Arcadia, on "Prevention and Control of Venereal Diseases"; Daniel F. H. Murphy, St. Petersburg, "Pituitary Gland Dysfunction"; Charles L. Farrington, St. Petersburg, "Osteomyelitis," and Emile Woods, Tampa, "Low Blood Pressure and Pregnancy." After dinner, J. Hardin Peterson, U. S. Congressman, was to discuss "Current Legislation of Interest to the Medical Profession."

IDAHO

New Industrial Bureau Head.—Dr. Augustus F. Galloway Jr., Kellogg, has been appointed medical officer of the state bureau of industrial hygiene to succeed Dr. Samuel Weissross, Boise, who resigned to enter private practice in Spokane, Wash.

ILLINOIS

Fifty-One Deaths in Typhoid Outbreak.—Fifty-one deaths had occurred in the outbreak of typhoid at the state hospital for the insane near Manteno, the Chicago Tribune reported September 30. At this time fifty-five patients were said to be still under observation and eleven of them were suspected carriers.

Society News.—The Lee County Medical Society was addressed in Dixon September 21 by Drs. Guy S. Van Alstyne and James J. Callahan, Chicago, on "The Management of Breast Tumors" and "Fractures About the Elbow," respectively.—At a meeting of the Fulton County Medical Society in Canton September 21 Dr. Carlo S. Scuderi, Chicago, spoke on fractures.—Dr. Robert S. Berghoff, Chicago, discussed "Senile Ectasy—A Clinical Discussion of Vascular Changes" before the Cass County Medical Society, Rushville, September 20. The meeting was in honor of physicians of the county who have been in the practice of medicine for fifty years.—Dr. Carl F. Vohs, St. Louis, discussed "Medical Economics in Relation to General Practice" before the Sangamon County Medical Society, Springfield, September 7.—At a meeting of the Peoria City Medical Society September 19 Dr. Laurence H. Mayers, Chicago, spoke on "Differential Diagnosis of Acute Abdominal Pains."

Chicago

Society News.—The Illinois Association for the Crippled Inc. will hold its third annual meeting at the Knickerbocker Hotel October 10 under the presidency of Dr. Edward L. Comper.

University of Chicago News.—Dr. Parker Dooley, assistant professor of pediatrics, Cornell University Medical College, New York, has been appointed assistant professor of pediatrics in the School of Medicine of the Division of Biological Sciences, University of Chicago, it is announced. Dr. Francis B. Gordon, assistant professor of bacteriology at the university, will return to the faculty this fall after a year's study with Dr. Christopher H. Andrewes at the National Institute for Medical Research, London. Subjects of new courses at the university include forensic medicine, background study of human evolution and abnormalities of voice and speech.

Scientific Programs of the Chicago Medical Society.—The Chicago Medical Society is planning a series of all day programs to be held on the third Wednesday of each month from October through April. There will be clinics, demonstrations, lectures and round table discussions on the general subject. The day portion of the program will be held in one or another of the teaching institutions of the city. The evening meetings will be held at the Chicago Woman's Club Theater on Eleventh Street near Michigan Boulevard. Detailed programs will be furnished each month. The topics to be considered at these meetings are:

- October 18, Fractures at the Cook County Hospital. 8:30 p. m., The Treatment of Skull Fractures, Dr. Harry E. Mock.
- November 15, Nutritional Deficiency Diseases at Thorne Hall, the Chicago Campus of Northwestern University. 8:30 p. m., The Vitamin B Complex and Pellagra, Dr. Tom D. Spies, Cincinnati.
- December 20, Cardiovascular-Renal Diseases (place not decided). 8:30 p. m., Arteriosclerosis Obliterans: The Modern Conception of Its Social Significance, Diagnosis and Treatment, Dr. Irving S. Wright, New York.
- Jan. 17, 1940, Industrial Medicine and Traumatic Survey at St. Luke's Hospital. 8:30 p. m., Evaluation of Disability Due to Cardiovascular Disease.
- Feb. 21, 1940, Topic and speaker to be selected.
- March 20, 1940, Endocrinology at the University of Chicago Clinics. 8:30 p. m., Misuse of Biologicals in Medical Practice.
- April 17, 1940, Obstetrics and Care of the New-Born. 8:30 p. m., Maternal and Infant Mortality in Chicago, 1935-1939.

A luncheon for members and guests will be arranged at or near the institution in which the clinical program is to be presented. A dinner will be held at the Chicago Woman's Club before the evening meetings. Members and guests are advised that admission will be by ticket only. Tickets must be obtained not later than the Saturday preceding the meeting. The price of the luncheons will be 50 cents and of the dinners \$1.50. For clinic, luncheon and dinner tickets apply to the Chicago Medical Society, 30 North Michigan Avenue, Chicago, phone Central 3026. All members of the Illinois, Wisconsin, Iowa, Indiana, Michigan and other state medical societies are cordially invited to attend these all day programs.

INDIANA

Changes at Indiana University.—Dr. David A. Boyd Jr., instructor in psychiatry and assistant physician in the Neuro-psychiatric Institute, University of Michigan Medical School, Ann Arbor, has been appointed head of the department of mental and nervous diseases of the Indiana University School of Medicine and Medical Center, Indianapolis, and Dr. LaRue Carter, member of the school faculty since 1914, has been named chairman of the division of neurology in the same department. According to the announcement, growth of the department under the leadership of Dr. Max A. Bahr, superintendent of the Central State Hospital, Indianapolis, has made the selection of a full time director necessary, although Dr. Bahr will continue with the department so far as his duties at the hospital permit.

KANSAS

Postgraduate Course on Heart Disease.—A five day postgraduate course on the study of heart disease will be held in Emporia this month, according to an announcement from the state medical society. Dr. David Scherf, New York, will conduct the course.

Society News.—Dr. George F. Green, South Bend, Ind., discussed "Factors Tending to Reduce the Mortality in Appendicitis" before the Shawnee County Medical Society, Topeka, September 11.—At a joint meeting of the Wyandotte County Medical Society and the Kansas City Veterinary Society September 19 the speakers were Dr. Louis B. Gloyne and F. B. Croll, D.V.M., on prevention and treatment of rabies. The medical society was addressed September 5 by Drs. Albert J. Rettenmaier on "Pelvic Appendicitis" and Maurice A. Walker, "Use of Barbiturates in Surgery."

Personal.—Dr. John A. Billingsley, Kansas City, has been appointed state ophthalmologist for the division of the blind by the Kansas State Board of Social Welfare, succeeding Dr. Clifford J. Mullen, who resigned September 1. Dr. Mullen was the first appointee after the department was organized.—Drs. Henry N. Tihen, Wichita, Noble E. Melencamp, Dodge City, and Hugh A. Hope, Hunter, have been appointed to the medical advisory committee of the Norton Sanatorium for Tuberculosis. Drs. Forrest L. Loveland and Fred P. Helm, Topeka, the latter ex officio as secretary of the state board of health, retain their membership until 1940.

Lectures on Medical History.—A course on medical history will again open the library and museum of medical history at the University of Kansas School of Medicine, Kansas City, it is announced. Lecturers in the course include:

- Dr. Sanford V. Larkey, librarian, William H. Welch Medical Library, Johns Hopkins University School of Medicine, Baltimore, October 9, Primitive Medicine; Egyptian Medicine.
- Dr. John Farquhar Fulton, Sterling professor of physiology, Yale University School of Medicine, New Haven, Conn., Jan. 15, 1940, History of Physiology.
- Dr. Henry E. Sigerist, William H. Welch professor of the history of medicine and director of the Institute of the History of Medicine at Johns Hopkins, March 4, 1940, The Future of Medicine in the Light of History.
- Chauncey D. Leake, Ph.D., librarian of the medical school library, lecturer in medical history and bibliography, and professor of pharmacology, University of California Medical School, San Francisco, March 11, 1940, The History of the Development of Therapeutic Drugs; The History of Anesthesia.

LOUISIANA

Personal.—Dr. Thomas C. Paulsen has been appointed physician to the Louisiana State University, Baton Rouge, and medical director of its hospital.—Dr. Roy W. Wright has been appointed director of Charity Hospital, New Orleans, to fill the vacancy left by the death of Dr. George S. Bel. Drs. Charles B. Odom and Joseph O. Weilbaecher Jr. were named assistant directors.

New Dean at Louisiana Medical Center.—Dr. Beryl I. Burns, since 1932 professor and head of the department of anatomy, Louisiana State University Medical Center, New Orleans, has been appointed dean of the school to succeed Dr. Joseph Rigney D'Aunoy, who resigned in August. Born in Missouri, Dr. Burns graduated at the State University of Iowa College of Medicine, Iowa City, in 1924; he took a degree of doctor of philosophy at Northwestern University Medical School, Chicago, in 1933. He has served on the teaching staffs of the University of Michigan Medical School, Ann Arbor, Iowa college of medicine and the University of Utah School of Medicine, Salt Lake City, where he served as dean from 1929 to 1932. Dr. D'Aunoy had been serving as dean of the medical school, pathologist and director of laboratories at Charity Hospital and professor of pathology and bacteriology. In his letter of resignation he intimated

that the fulfilment of all these offices would endanger his health but asked to remain active as medical consultant to Charity Hospital and as professor in the medical school. Immediately after Dr. D'Aunoy's resignation an executive committee was appointed comprising Drs. Urban Maes as chairman, John R. Schenken, Edgar Hull, James T. Nix, Richard Ashman, Ph.D., and Dr. Burns. On Dr. Burns's appointment as dean, it was decided to continue the executive committee to be active in all school affairs. Dr. Schenken was appointed to a newly created position as assistant to the dean.

MARYLAND

Personal.—Dr. Daniel H. Kress and his wife, Dr. Lauretta E. Kress, recently marked their retirement from active practice with a farewell gathering on the lawn of Washington Sanitarium, Takoma Park, where they have been on the staff for thirty-two years. They will live in Orlando, Fla.

Camp for Diabetic Children.—The third annual camp for diabetic children was held at the Christ Child Farm for Convalescent Children, Rockville, during August. Diabetic children of limited means, 6 to 12 years of age, were eligible. The camp was under the supervision of Drs. Eugene Clarence Rice Jr., Kemp Hammond Mish, Samuel Benjamin and Benjamin Manchester, Washington, D. C.

Anonymous Donor Aids Venereal Disease Control.—A model program on venereal disease control was formally launched in Centerville recently, with Dr. Thomas Parran, surgeon general, U. S. Public Health Service, officiating. According to *The Health Officer*, federal and state funds for the support of this program will be supplemented by an anonymous donor's contribution of \$10,000 a year for the next three years.

Semiannual Meeting of Medical and Chirurgical Faculty.—The semiannual meeting of the Medical and Chirurgical Faculty of the State of Maryland was held at the Vindobona Hotel, Braddock Heights, Frederick County, September 28. Dr. Victor F. Cullen, acting president of the faculty, delivered the address of welcome. The speakers included:

- Dr. Royd R. Sayers, Washington, D. C., The Health of Workers.
- Dr. Harry H. Kerr, Washington, D. C., A Solution for Our Medical Economic Problem.
- Dr. Horace L. Hodes, Baltimore, Treatment of Pneumonia with Sulfapyridine.
- Dr. Robert H. Riley, Baltimore, The State Pneumonia Program.

Dr. Ridgely W. Baer, Frederick, president of the Frederick County Medical Society, also spoke.

MICHIGAN

Personal.—Dr. August C. Orr, who has been director of the child hygiene division of the North Dakota state department of health, has been appointed director of the sixth district of the Michigan State Department of Health with headquarters in Newberry.—Dr. Clark D. Brooks, Detroit, has been appointed a member of the Detroit Board of Education to serve the unexpired term of the late Dr. Angus McLean.

Society News.—The nineteenth annual Michigan Public Health Conference will be held at the Pantlind Hotel, Grand Rapids, November 8-10.—Dr. Fred J. Hodges, Ann Arbor, addressed the Genesee County Medical Society, Flint, September 27 on "Neoplasms of the Stomach."—Dr. Charles F. Geschickter, Baltimore, discussed "Conditions of the Breast" before the Calhoun County Medical Society, Battle Creek, September 5.

MINNESOTA

Personal.—Dr. Russell H. Frost, Wabasha, has resigned as superintendent and medical director of Buena Vista Sanatorium to accept a similar position at the G. B. Cooley Sanatorium, Monroe, La. Dr. Russell R. Hendrickson, St. Cloud, who was superintendent of Fair Oaks Lodge Sanatorium, Wadena, for several years, has succeeded Dr. Frost at Buena Vista.—Dr. Alloys F. Branton, Willmar, has been appointed executive secretary of the Minnesota Hospital Association.

Field Clinics for Crippled Children.—Field clinics were held in Worthington September 9, the first of a series conducted throughout the state by the bureau of services for crippled children of the state social security board. Cooperating with the bureau are the Minnesota Public Health Association, the division of rehabilitation of the state department of education and Gillette State Hospital. Other clinics were held in Hibbing September 16, Marshall September 23, Winona September 30 and Bemidji October 7. They will be held also at Fergus Falls October 28 and Mankato November 18. Mem-

bers of the Minnesota-Dakota Orthopedic Club are serving as clinicians. A letter from the attending physician of the patient is all that is required for entrance to the clinic, which is open to all physically handicapped children under 21 years of age whose parents cannot provide the needed care.

MISSOURI

Society News.—At a meeting of the St. Joseph Clinical Society in St. Joseph, September 14, Drs. Earl M. Shores, Jacob Kulowski and Leon Paul Forgrave presented a symposium on arthritis and Drs. Horace W. Carl, Judson M. Hughes and Frederick Gregg Thompson one on the acute abdomen. Dr. Winton T. Stacy discussed "Toxemias of Pregnancy." In the evening, Dr. Morris Fishbein, Chicago, Editor of *THE JOURNAL*, spoke on "American Medicine and the National Government." This was a joint meeting and dinner with the Buchanan County Medical Society.

NEW JERSEY

Society News.—Dr. John A. Kolmer, Philadelphia, addressed the Gloucester County Medical Society, Woodbury, in September on "Advances in the Treatment of Bacterial Diseases, with Special Reference to Sulfanilamide."—Dr. William Wolf, New York, addressed the Bergen County Medical Society at Englewood Hospital September 12 on practical endocrinology.

State Society to Investigate Deaths of Motorists.—The committee on traffic accidents of the Medical Society of New Jersey has asked county societies to investigate sudden deaths and illnesses of persons driving automobiles. The committee hopes by this means to determine which types of persons are potential hazards to themselves and others while driving a car. It is believed that data will be obtained that will be useful to the state motor vehicle department. A list of suggested questions to be answered in connection with each case was prepared by the committee. Among them were the following: If the case did not involve the death of the driver, what was the diagnosis of the illness? Would, in your opinion, a physical examination at the time the license was issued have revealed the diagnosis? Would the physical examination have revealed sufficient evidence to warrant a refusal of license on the basis that the driver might constitute a hazard to himself or to others? Should this driver have been denied a license on the basis of a known physical defect?

NEW YORK

Poliomyelitis in Buffalo.—Eight new cases of poliomyelitis reported in Buffalo September 28 brought the total number of cases in the current outbreak there to 273, with eight deaths. Opening of schools, scheduled for September 6, was postponed on the advice of the board of health. Schools in the adjacent towns of Batavia, Oakfield, Alden, Alexander and Pavilion have been closed after operating from two to three weeks. About forty cases have occurred in Batavia.

District Meeting.—The Third District Branch of the Medical Society of the State of New York held its annual meeting September 22-23 in Liberty. The speakers were:

- Dr. George G. Ornstein, New York, Diagnosis of Carcinoma of the Lung.
- Dr. Louis R. Davidson, New York, Pneumonectomy in Man.
- Dr. Jesse G. M. Bullowa, New York, Specific Therapy of the Pneumococcal Pneumonias.
- Dr. Arthur H. Blakemore, New York, Wiring and Electrothermic Coagulation of Aneurysms.
- Dr. Howard K. Thompson, Boston, Chronic Arthritis from the Standpoint of the Practicing Physician.
- Drs. Charles M. Carpenter and Stafford L. Warren, Rochester, N. Y., Biologic and Therapeutic Effects of Artificially Induced Fever.
- Dr. Clay Ray Murray, New York, Problem Fractures About the Elbow Joint.

Dr. Terry M. Townsend, New York, president of the state society, gave an address at an informal dinner.

New York City

Society News.—At the first stated meeting of the New York Academy of Medicine for this season October 5 the subject of discussion was "Treatment of Pyogenic Infections with Special Reference to Chemotherapy." Dr. Emanuel Libman introduced the discussion; Drs. Dallas B. Phemister, Chicago, and Edmund P. Fowler Jr., spoke on "Osteomyelitis" and "Otitis Media and Its Extensions," respectively.

Friday Afternoon Academy Lectures.—The fourteenth series of Friday afternoon lectures at the New York Academy of Medicine will begin November 10 with an address by Dr. John Russell Twiss on "Medical Management of Disorders

of the Biliary Tract." The series for the remainder of this year will be as follows:

- Dr. Harry Gold, Treatment of Cardiac Arrhythmias with Special Consideration of Paroxysmal Tachycardia.
- Dr. Richard A. Kern, Philadelphia, The Treatment of Visceral Allergies.
- Dr. Allen O. Whipple, Surgical Indications in Disorders of the Gallbladder.
- Dr. Alvan L. Barach, Recent Advances in Helium and Oxygen Therapy; Principles and Methods.

Diseases Under Investigation at Rockefeller Institute.

—The Hospital of the Rockefeller Institute for Medical Research announces the diseases now under investigation and invites physicians to refer cases suitable for study. These diseases are nephritis, heart disease, rheumatic fever, measles and acute respiratory diseases. Young children with nephrosis are especially desired and patients with nephritis in the initial acute stages will be accepted if space is available. Older patients with advanced heart disease, any early acute form of rheumatic fever, measles in the preeruptive stage, acute lobar pneumonia and bronchopneumonia in adults, both preferably in early stages, are also desirable. No charges are made for treatment, room, board or other services. Physicians should communicate with the resident physician before sending patients.

NORTH CAROLINA

New Dean at Nursing School.—Miss Margaret I. Pinkerton, superintendent of nurses at Barnes Hospital, St. Louis, has been appointed dean of the school of nursing at Duke University, Durham. Miss Pinkerton took the degree of bachelor of science in nursing from Teachers College, Columbia University, New York, in 1933 and held administrative positions at Stuart Circle Hospital, Richmond, Va., University of Virginia, Charlottesville, and Washington University, St. Louis, before going to Barnes Hospital.

Society News.—Dr. Franklin Webb Griffith, Asheville, addressed the Buncombe County Medical Society, Asheville, September 18 on "Urgent Surgery on Infants."—Dr. Joseph Lindsay Cook, Winston-Salem, addressed the Guilford County Medical Society, High Point, recently on "Advances in the Treatment of Syphilis."—Speakers before the meeting of the Catawba Valley Medical Society, Morganton, September 12 were Drs. Walter Eugene Daniel, Charlotte, on "A Comparison of Sulfanilamide, Sulfapyridine and Sulfanilyl-Sulfanilamide"; Joseph Samuel Holbrook, Statesville, "Recent Advances in the Diagnosis and Management of Cardiovascular Diseases," and Kenneth Lee Cloninger, Conover, who reported a case of myasthenia gravis.

OREGON

Society News.—Dr. Samuel G. Henricke, Portland, was elected president of the North Pacific Pediatric Society at a meeting in Spokane August 26; Dr. Morris L. Bridgeman, Portland, was made vice president and Dr. Jerald S. Backstrand, Salem, secretary.

State Medical Election.—Dr. Karl H. Martzloff, Portland, was chosen president-elect of the Oregon State Medical Society at the annual meeting in Gearhart September 6-9 and Dr. Charles E. Hunt, Eugene, was installed as president. Vice presidents elected were Drs. George E. Henton, Portland; Frank L. Ralston, La Grande, and Frank K. Power, Salem. Dr. Morris L. Bridgeman, Portland, was reelected secretary and Dr. James E. Buckley, Portland, was elected treasurer.

PENNSYLVANIA

Clinic Day Honors Hungarian Surgeon.—The Guthrie Clinic and the Robert Packer Hospital, Sayre, held a graduate clinic August 9 in honor of Dr. Lajos Adam, professor of surgery, University of Budapest. The speakers were:

- Professor Adam, Experiences with Local Anesthesia in General Surgery.
- Dr. William D. Stroud, Philadelphia, Coronary Disease Including Angina Pectoris and Its Differential Diagnosis from Gallbladder Disease; the Indications for Digitalis and Its Administration.
- Dr. John F. Erdmann, New York, Surgery of the Gallbladder.
- Dr. Walter E. Dandy, Baltimore, Injuries of the Head.
- Dr. Jesse G. M. Bullowa, New York, Treatment of Pneumonia with Sulfapyridine.

Society News.—Physicians from the University of Pittsburgh School of Medicine, Pittsburgh, presented a program before the Venango County Medical Society, Franklin, September 15. They were Drs. George J. Wright on "Gastrointestinal Manifestations of Neurologic Diseases"; Morris A. Hershenson, "Diagnosis and Medical Treatment of the Commoner Gastrointestinal Diseases"; John P. Griffith, "Indications for Surgical Intervention in Gastrointestinal Diseases," and Curtis C. Mechling, "Proctology for the General Practitioner."—Dr. Arthur C. Morgan, Philadelphia, addressed the Fayette County Medical Society, Connellsville, September 7 on

medical education.—Dr. Henry Joseph Tuncu, Philadelphia, addressed the Cambria County Medical Society, Johnstown, September 14 on "Management of an Irritable Colon."—Dr. Thomas R. Gagon, Pittston, addressed the Northampton County Medical Society, Easton, September 15 on "The Eye Findings in General Disease."—Dr. Lloyd E. Wurster, Williamsport, addressed the Lycoming County Medical Society, Williamsport, September 8 on "Opportunities for Mutual Benefit and Cooperation Between Roentgenologist and Practitioner," and Dr. Lee M. Goodman, Jersey Shore, reported a case of typhoid.—Dr. Calvin M. Smyth Jr., Philadelphia, addressed the Harrisburg Academy of Medicine September 19 on surgical diagnosis.

TENNESSEE

Society News.—Drs. Robert H. Miller, Memphis, and Robert S. Cowles, Greeneville, addressed the Greene County Medical Society, Greeneville, August 1 on "Some Points on the Mechanics of the Body, Especially the Lower Extremity" and "Tularemia" respectively.—At a meeting of the Hardin, Lawrence, Lewis, Perry and Wayne Counties Medical Society at Natural Bridge recently the speakers were Drs. John Howard King, Nashville, on "The Commoner Skin Diseases"; John H. Tilley, Lawrenceburg, "Traumatic Injury of the Liver with Report of a Case," and David W. Hailey, Nashville, "Undulant Fever."—Dr. Arthur R. Kempf, Springfield, discussed "Urogenital Diseases" before the Robertson County Medical Society in Cedar Hill recently. Dr. Bailey B. Sory entertained the members with a barbecue.—Dr. Guy Sydney McClellan, Nashville, addressed the Nashville Academy of Medicine and Davidson County Medical Society September 5 on leukorrhea, and Dr. Clarence S. Thomas, September 12, bronchiectasis.

TEXAS

Personal.—Dr. Albert M. Dashiell, Bryan, recently director of the fourth public health district, has been appointed field director of maternal and child health.—Dr. Clarence Burke Brewster, Fort Worth, has been made city health officer to succeed the late Dr. Arthur H. Flickwir. Dr. Isaac P. Barrett succeeded Dr. Brewster as health director of the public schools in Fort Worth.

Society News.—Dr. Frank C. Hodges, Abilene, addressed the Baylor-Knox-Haskell Counties Medical Society August 15 in Munday on "Fractures of the Hip."—Drs. R. R. Curtis and Joseph H. Greenwood, Temple, addressed the Bell County Medical Society recently in Belton on "X-Ray Diagnosis of Diseases Affecting the Chest" and "Vitamin K" respectively.—Dr. Henrie E. Mast, Lubbock, discussed cystoscopy at a meeting of the Lubbock-Crosby Counties Medical Society in Lubbock August 1.—Speakers before the Dallas County Medical Society, Dallas, September 14, were Drs. Charles B. Shuey on "Allergy"; Charles H. Warren, "Amebic Abscess of the Liver," and Paul M. Wolff, "Surgical and Nonsurgical Treatment of Women's Diseases."

VIRGINIA

New Health Officers.—Dr. Philip R. Cronlund, Washington, D. C., has been made health officer of Lee County to succeed Dr. James M. Suter, Jonesville, who will attend Johns Hopkins University for the coming year. Dr. William M. Moir, Indianapolis, replaces Dr. Earle C. Gates in Washington County and Bristol; Dr. Gates will also spend a year at Johns Hopkins. Dr. Thomas S. Englar, Baltimore, appointed in Albemarle County and Charlottesville, succeeds Dr. Robert D. Hollowell, who has gone to Shelby County, Tenn., and Dr. Marvin E. McRae, Richmond, succeeds Dr. Eugene B. Shepherd, Chatham, resigned, in Pittsylvania County.

WASHINGTON

Personal.—Dr. Floyd W. Baugh, Burlington, has been appointed health officer of Skagit County. Dr. Adolph J. Osterman, Mount Vernon, has served temporarily since the death of Dr. Benjamin F. Brooks.—Dr. William E. Steele, Longview, has been appointed chief medical adviser to the state department of labor and industries, a position he held several years ago.

Society News.—Dr. Paul G. Flothow, Seattle, addressed the Pierce County Medical Society, Tacoma, September 12 on "Affections of the Sympathetic Nervous System."—Drs. Robert D. Forbes and Cassius H. Hofrichter addressed the King County Medical Society, Seattle, October 2, on "Digestion After Gastric Resection" and "The Liver and Bile Passages from a Medical Standpoint" respectively.—Dr. Walter

L. Voegtlin, Seattle, addressed the Spokane County Medical Society, Spokane, September 14 on "Treatment of Alcoholism by Establishing a Conditioned Reflex." Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, addressed a special meeting of the society September 25.

WISCONSIN

Society News.—Drs. William H. Oatway Jr. and Reuben H. Stichm addressed the University of Wisconsin Medical Society, Madison, September 26 on "Mechanical Aids to Collapse Therapy in Pulmonary Tuberculosis" and "Subclinical Tuberculosis" respectively. Dr. Carl Erik Johan Hedvall, director of the tuberculosis clinic at the University of Lund, Sweden, was to have been the speaker but was compelled to leave for Sweden before the meeting.

GENERAL

Biological Abstracts Widens Scope.—Announcement is made that *Biological Abstracts* is undertaking a wider service in abstracting current research literature in bioclimatology and biometeorology. A new section "Bioclimatology-Biometeorology" will appear within the section "Ecology" under the editorship of Mr. Robert G. Stone, of the Blue Hill Observatory of Harvard University.

Allotment of Government Radium to Hospitals.—The first shipments of government-owned radium from the National Cancer Institute to hospitals have been made, the U. S. Public Health Service announced September 25. The entire supply of radium has now been allotted and no more applications can be considered until more radium is acquired. Eight Gm. is being lent and the remaining supply owned by the cancer institute, 1.5 Gm., will be used for research and for treatment of cancer patients at the Marine Hospital in Baltimore.

Bequests and Donations.—The following bequests and donations have recently been announced:

Presbyterian Hospital, New York, approximately \$843,000 by the will of Susan Dannatt Griffith.

Hospital for Joint Diseases, New York, about \$33,000 by the will of the late Fanny Bachrach.

Temple University Hospital, Philadelphia, \$22,000 by the will of Evelyn Shearer.

Women and Children's Hospital, Chicago, \$10,000 by the will of Mrs. Emma L. Dickinson.

Jewish Hospital, \$5,000; Lucian Moss Home for Incurables of the Jewish Hospital, \$7,500; University Hospital, \$1,000, all in Philadelphia; Eagleville Sanatorium for Consumptives, Eagleville, Pa., \$5,000, and National Jewish Hospital, Denver, \$1,000 by the will of Miss Rosa Cohen.

Two Impostors.—A Chicago physician has reported another case of the impostor who takes orders for surgical supplies. The man reported claimed to be a representative of Hayes and Company, Indianapolis, and took a deposit of \$2 on an order for surgical supplies. A letter addressed to the "Hayes" firm several weeks later was returned marked "undeliverable."

—From Michigan comes a report of a man who called on a physician to ask for a loan because his car had broken down. The would-be borrower claimed to be "Dr. Riley" of Flint and declared that he was a classmate of his victim, who lent him \$10. Becoming suspicious after the "classmate" left, the physician, who did not remember the man, looked him up in the medical directory and did not find his name. He immediately called his bank to stop payment on the check, but the check had already been cashed. Later it was found that other physicians had been victimized the same way.

Mead Johnson Award for Vitamin Research.—The American Institute of Nutrition announces that nominations will be received for the 1940 award of \$1,000 established by Mead Johnson & Co. to promote research on the B complex vitamins. The recipient will be chosen by a committee of the institute and the formal presentation will be made at the annual meeting in New Orleans March 13, 1940. The award will be given to the laboratory (nonclinical) or clinical research worker in the United States or Canada who in the opinion of the judges has published during the previous calendar year, January 1 to December 31, the most meritorious scientific report dealing with the field of these vitamins. If in the judgment of the committee circumstances and justice dictate it, the prize may be divided between two or more parties. It may also be recommended that the award be made to a worker for valuable contributions over an extended period but not necessarily representative of a given year. Nominations for work published in 1939 must be in the hands of the secretary by Jan. 5, 1940. The nomination should be accompanied by such data relative to the nominee and his work as will facilitate the task of the committee in its consideration. Leonard A. Maynard, Ph.D., Laboratory of Animal Nutrition, Cornell University, Ithaca, N. Y., is secretary of the institute.

Nine Leading Causes of Death.—The Bureau of the Census has made public a study of the 1,450,427 deaths reported in 1937 showing that nine groups of diseases caused 72 per cent of all the deaths. The causes are: diseases of the heart 23.9 per cent; influenza and pneumonia 10.2; cancer and other malignant tumors 10; nephritis 7.1; cerebral hemorrhage and softening 6.9; tuberculosis (all forms) 4.8; congenital malformations and diseases of early infancy 4.4; motor vehicle accidents 2.7, and diabetes mellitus 2.1. The report also classifies the deaths by age groups and presents the leading causes of death in each group. Congenital malformations and diseases of early infancy accounted for 51.4 per cent of deaths under 1 year. In early childhood (1 to 4 years) influenza and pneumonia led with 26.9 per cent. Influenza and pneumonia also caused most deaths in youth (5 to 19 years), 12.6 per cent, with motor vehicle accidents second, 10.9 per cent. From 20 years onward heart disease leads all other causes, with 18.7 per cent in the adult years (20 to 60) and 33.9 in the group 60 years and older. In the last two groups cancer is second with 11 and 12 per cent, respectively, of all deaths. Tuberculosis is a major cause of death in every age period except infancy; influenza and pneumonia appear at all ages. Drowning is an important hazard in the youth group alone and motor vehicle accidents loom largest at this age. In contrast to the 1,450,427 deaths, there were 2,203,337 births in 1937.

FOREIGN

Personal.—Drs. Alfred J. Clark, professor of materia medica, University of Edinburgh, Scotland, and Thomas R. Elliott, emeritus professor of medicine, University of London, have been appointed members of the Medical Research Council to succeed Prof. Henry S. Raper and John A. Ryle, who retire September 30, the *Lancet* reports.—Mr. William C. Wilson, director of the surgical research laboratory in the University of Edinburgh and of the surgical research unit in the Edinburgh Royal Infirmary, has been appointed to the regius chair of surgery at the University of Aberdeen, succeeding Dr. James R. Learmonth.

Deaths in Other Countries

Sir Frederick Spencer Lister, director of the South African Institute for Medical Research, Johannesburg, died September 6, aged 63.—Dr. George Redmayne Murray, emeritus professor of medicine, Victoria University, Manchester, England, died September 23 at Moberly, Cheshire, England.

CORRECTION

Head of Department of Pathology.—In the Educational Number of THE JOURNAL August 26, page 852, Dr. C. C. McClure, radiologist, Vanderbilt University Hospital, Nashville, Tenn., was erroneously listed as head of the department of pathology. Dr. E. W. Goodpasture is chief of that service.

Government Services

New Army Medical Officers

The following officers of the Medical Reserve Corps, U. S. Army, have been commissioned as first lieutenants in the Medical Corps:

Robert S. Anderson, Fort Myer, Va.	Alva E. Miller, St. Joseph, Mo.
Austin W. Bennett, Templeton, Calif.	Charles K. Morris, Binghamton, N. Y.
George S. Boyer, Fort Riley, Kan.	Myles P. Moursund, Silver Spring, Md.
James W. Brown, Whitefish, Mont.	Byron A. Nichol, Portland, Ore.
Leo J. Butler, San Francisco.	Lawrence A. Potter, La Crescenta, Calif.
Roosevelt Cafarelli, Amherst, Va.	Donald E. Reiner, Santa Maria, Calif.
Richard B. H. Dear, Fort Bragg, N. C.	Ralph E. Reiner, Santa Maria, Calif.
William N. Donovan, Fort Moultrie, S. C.	Hallman E. Sanders, Hot Springs National Park, Ark.
Carl N. Ekman, St. Paul.	Alton H. Saxer, Logan, Utah.
Wolcott L. Etienne, Washington, D. C.	Howard E. Sellards, Fort McClellan, Ala.
Everett C. Freer, Fort George G. Meade, Md.	Paul C. Sheldon, Terre Haute, Ind.
Wendell P. Harris, Hot Springs National Park, Ark.	Rolland B. Sigafos, Omaha.
Wilbur W. Hiehle, Ancon, C. Z.	John M. Talbot, Portland, Ore.
Kenneth E. Hudson, Yale, Okla.	Frederick C. Weekley, Dallas, Texas.
Robert L. Houghton, New Orleans.	Francis P. Wells, Washington, D. C.
Nathan F. Kane, Norfolk, Va.	
William W. Lister, Denver.	
George G. McShatko, Portland, Ore.	
Ralph L. Marx, Pawnee, Okla.	

Foreign Letters

LONDON

(From Our Regular Correspondent)

Sept. 16, 1939.

The Problem of Medical Literature

In a previous letter (THE JOURNAL, August 26, p. 868) a lengthy correspondence in the *Lancet* on the problem of medical literature, in which medical writers and medical librarians took part, was described. The problem is the extent of medical literature and the difficulty a writer has in gaining access to what has been written on a particular subject, notwithstanding the *Quarterly Cumulative Index Medicus* and the *Surgeon General's Index Catalogue*. One practical suggestion which emerged was the coordination of medical libraries, which has already been begun by four libraries in London. The correspondence has been continued and the *Lancet* has joined in the fray by an editorial entitled "The Mess of Medical Literature." Earlier in the year it estimated the number of scientific periodicals in the world as between 30,000 and 40,000. A large proportion of the papers in them—some would say three fourths—did not deserve to be published. An estimate was not given of the number of medical periodicals or of the proportion of their papers which do not deserve publication. Three suggestions were made by the *Lancet*: (1) some control over the volume of medical literature, (2) an effort to ensure complete indexing, (3) cooperation between abstracting journals to secure completeness without overlapping. Of the two great American indexes to which we are indebted, the *Lancet* says that the *Quarterly Cumulative Index Medicus* does not include all existing medical periodicals or the titles of all the articles in the indexed periodicals, and that the *Index Catalogue* is even less complete, invaluable as it is for early records. Prof. Samson Wright (physiologist) dissents and says that the *Lancet* seems to argue that we must make available a copy of every medical journal published and criticizes the *Quarterly Cumulative Index Medicus* for not noting all the papers printed. He suggests that there is a better case for reducing the number of journals taken by our libraries and for the abstracting journals not to extend but to limit their scope. There is no need to bother with the journals of small countries, as their writers know their weakness from the point of view of world publicity and publish any exciting discovery in English, French or German journals or write reviews or lecture on the subject abroad. But the problem remains what to do with the journals published in the half dozen principal languages. Many of these journals publish no original matter at all or very little of the slightest value. In a country like Germany, where medical publications are almost the monopoly of one firm, where editorial supervision has always been notoriously inadequate and where stress has always been placed on bulk rather than quality, more and more journals are becoming wholly or largely valueless as sources of original material. A group of committees of experts should be set up to report on the journals in each specialty. If a journal should fail to reach a reasonable standard of merit, the libraries should cancel their subscription to it and the abstracting journals should ignore it. No investigator of standing would then send any contributions to it. The same weapon could be used to control new journals. But we do need competent medical abstracting service in the English language. It is preposterous that a library should have to pay \$750 a year for an abstracting service in German. We need a journal like *Physiological Abstracts*, which covers the whole field of medical science excepting purely clinical papers. Its subscription is only \$16, while that of the German equivalent, which publishes the same number of abstracts, is \$150. An

annual subsidy of \$15,000 for three years would establish "English Medical Abstracts." The Royal Colleges of Physicians and Surgeons and the Royal Society of Medicine and various learned societies could provide this.

Medical Service for the Civilian Population

The central and local emergency committees of the British Medical Association will be responsible during the war for the supply of medical personnel for the fighting forces and for the civilian population. The allocation of practitioners for first aid posts at home for the treatment of casualties from air raids is now complete, and the appointments to the civilian hospitals are almost complete. The first aid posts have been set up with the intention of protecting casualty hospitals from a rush of minor and ambulant cases and of providing early treatment in districts where the hospital is some distance away. The function of the first aid post is (1) to treat and send to their homes those who are slightly injured and those suffering from nervous shock; (2) to arrest hemorrhage, relieve pain and so prepare persons who may be found to need institutional treatment that they can be transferred to the casualty hospital with the least possible harm. A physician will be in charge of each first aid post who has instructed the lay personnel workers under his control.

TETANUS ANTITOXIN

The Ministry of Health Emergency Service has recommended that as far as possible all persons with open wounds shall receive a prophylactic dose of tetanus antitoxin, which is being stored at more than fifty centers throughout England and Wales so as to be quickly available for use both at the first aid posts and at hospitals. While some authorities have advocated a prophylactic dose thrice that used with marked success in the great war, it is considered that a smaller one may be adequate. The dose recommended is therefore 2 cc. of the liquid serum provided, which at present represents 2,600 international units. This should be administered at the first medical unit at which the injured person is received. To avoid anaphylactic reactions, a second dose should not be given. The prophylactic antitoxin is in bottles containing fifteen or thirty doses. For treatment antitoxin is supplied in single sealed ampules containing not less than 20,000 (actually 24,000) international units in a volume not exceeding 8 cc.

GAS GANGRENE ANTITOXIN

Supplies of gas gangrene antitoxin are being held in the big centers throughout the country and will be available for surgeons whenever required. The arrangements allow for the administration of Welch, Vibron septique and Oedematiens antitoxins either separately or combined. While little is known regarding the dosage for prophylaxis and therapy, the provisional proposal, which may have to be modified in the light of experience, is to administer 1,000 units of Welch, 1,500 of Vibron septique and 1,000 of Oedematiens antitoxin as a combined injection for cases in which the surgeon desires to combine serum prophylaxis with surgical treatment. This combined treatment is contained in a volume not exceeding 10 cc. For treatment a combined injection containing not less than 7,500 units of Welch, 3,750 of Vibron septique and 2,500 of Oedematiens is recommended. For cases in which the causal organism has been identified, supplies of the separate antitoxins are available.

TREATMENT OF SPECIAL TYPES OF INJURY

It is proposed to provide special centers at which certain types of disability can be collected and treated by the appropriate specialist staff. But in the early stages of an emergency it is considered likely to be impracticable to switch over suddenly from a central peace-time to a decentralized war-time

organization. While, therefore, it will at first be necessary to treat any type of case at the advanced base hospitals, special centers will be established as soon as possible. In the case, however, of the neuroses uncomplicated by any injury, endeavor must be made from the outset to send those requiring special treatment to special institutions.

Report of Public Health Service in Germany

The report on the public health service, prepared by the division of public hygiene of the reich's department of the interior, has appeared. Austria and the Sudetenland are not included in the report. Officially the report is designated as "interpretative and determinative of the health development of the entire German people."

The number of marriages has somewhat increased (from 618,971 to 644,363; that is, from 9.1 to 9.4 per thousand), though the opposite was to be expected in view of the considerably reduced birth rate during the World War. Vital statistics pertaining to births yield the following figures: 1937, 1,275,212, in the whole country 18.8 per thousand; 1938, 1,346,911, in the whole country 19.7 per thousand. Families with two and three children still appear everywhere to be on the increase. The general mortality rate has remained almost unchanged (11.7 per thousand). Stillbirths and infant mortality have continued to decrease: 2.3 stillbirths per hundred born alive (2.4 per hundred in 1937); 6 per hundred infant deaths during the first year (6.4 per hundred in 1938). Individual causes of deaths of nurslings compared with those of 1937 show a slight reduction per thousand; syphilis, however, a slight increase of from 0.21 to 0.23. Mortality from intestinal catarrh receded from 5.72 to 5.59. Likewise, premature deaths resulting from premature births and low vitality were fewer (30.89 as compared with 32). While scarlet fever declined in the last three years, diphtheria showed a further advance. The increase in measles may signify the beginning of another rising wave. The same may apply to whooping cough, which however shows a heightened mortality. Epidemic meningitis has risen considerably: 1,826 cases in 1938 against 1,574 in 1937 and 1,322 in 1936. Nothing definite is known of the causative factors. Epidemic poliomyelitis has greatly increased, especially in the Rhenish and south German areas, but mortality has decreased.

The morbidity and mortality rates for tuberculosis have further declined; notably that of tuberculosis of the respiratory organs: tuberculous diseases in 1937 numbered 63,570; in 1938, 60,420. The morbidity rate for tuberculosis of the respiratory organs per 10,000 inhabitants was 8.9 in 1938 against 9.4 in 1937; the mortality rate was 5.4 in 1938 as compared with 6 in 1937. The total mortality rate for tuberculosis of all kinds was 6.3 in 1938 compared with 6.9 in 1937. Typhoid showed a further slight decrease in morbidity but took a relatively larger toll of lives (in 1938, 11.5 per hundred cases; in 1937, 9.9). Paratyphoid and epidemic dysentery show a similar picture. The morbidity and mortality rates for puerperal fever and febrile miscarriages have fallen somewhat except for puerperal fever in large cities (209 in 1938 against 192 in 1937). Deaths from influenza receded from 1.3 to 0.9 per 10,000 inhabitants. The nation was spared a more serious epidemic of influenza in 1938. However, more deaths occurred from pneumonia due to influenza (1937, 8; 1938, 8.3). The higher age levels, no doubt, account considerably for this increase. Other infectious diseases show a decreased morbidity status: Trachoma, which in 1935-1937 was represented progressively by 611, 620 and 697 cases, fell to 533. There were eighty-four cases of anthrax in 1938 against ninety in 1937 (six deaths against seven in 1937); thirty-seven cases of psittacosis against

twenty-two in 1937 (six deaths). Trichinosis appeared in twenty cases without mortality. In the government district of Aurich (province of Hanover) there were 345 cases of malaria.

The number of suicides in large cities remained the same: 3 per 10,000 (6,419 in 1938 against 6,217 in 1937); that of fatal accidents rose from 6,851 to 7,486 (3.3 in 1937, 3.5 in 1938 per 10,000 inhabitants). This increase is attributed more to the spread of industries than to traffic congestion; in fact, fatal traffic accidents were 3 per cent fewer than in 1937. On the other hand, the number of those injured on the streets has increased by 4 per cent, that of street accidents, in general, by 3 per cent. However, the use of automobiles also increased by 15 per cent. Traffic fatalities mounted to 7,404, injuries to 181,254. In general, health conditions are reported as favorable. Infant mortality, as mentioned, has decreased. In individual districts the figures fluctuate between 11.5 per cent in poor mountain regions and 3.8 per cent. Serious cases of rickets are almost completely absent in the report.

Excessive propaganda for the use of flour in the nutrition of children is complained of. The education of mothers in infant nutrition has to contend with old customs, especially in the country, and makes progress slowly. Desire on the part of mothers to nurse their babies usually ceases when the government premium is no longer paid. Sometimes the necessity for resuming work is the cause. Reports on preschool children are generally favorable. The report on children of school age, in spite of its generally favorable tenor, points out posture defects, a tendency to scoliosis and flatfoot. Dental caries continues to be an unsatisfactory problem. The report on conditions of the nation's youth criticizes chiefly immoderate cigaret smoking and premature manual labor.

The most unfavorable sections in the report on adults concern farmers' wives. Hard manual labor and birth frequency are assigned as the reasons. The increased need of houses caused by increase in marriages and better knowledge of sanitation is far from being met despite active building. Sanitation is not what it should be in many regions, partly because married women are engaged in outside work, partly because of the large size of the families. However, some of this is due to a certain scarcity of water. The former lack of beds and bedding has now disappeared almost everywhere. The report on venereal diseases refers to the fact that syphilis is found in relatively fewer cases but that gonorrhea has considerably increased in many districts.

No increase of mental diseases is reported. However, a heightened nervousness in youths and adults is recognized. "A decidedly unpleasant picture is presented in the statistics of the use of alcohol and nicotine." More favorable economic circumstances and heavy advertising are held responsible for this. The fight against narcotics has yielded good results.

In spite of the energetic steps taken the number of abortions is everywhere deplorably high. This has led to still more extensive investigations. In 1938 a large number of physicians, midwives and persons in ordinary walks of life were sent to jail or the penitentiary. The number of miscarriages is also surprisingly high and is not exclusively due to the use of abortion, but largely, both in country and town, to the exceedingly unfavorable environment in which very young primiparas as well as hard working multiparas often have to live.

Medical Pact Between Germany and Japan

Motivated by Germany's and Japan's cultural pact, an agreement suggested by Japan has been signed in Tokyo looking forward to an exchange of German and Japanese physicians. For this purpose Dr. Haedenkamp, leader of the foreign division of Germany's chamber of medicine, is now visiting in Japan. This medical pact is primarily planned to deepen the intellectual relations between the two nations. Individual features of this pact are the exchange of physicians, reciprocal information

regarding the application of medical methods and legislation pertaining to social politics and public hygiene. The pact is provisionally limited to three years. By means of this pact the cooperation between the two countries in the field of medicine, in operation for decades, is to be continued.

OSLO

Sept. 12, 1939.

Manganese in Factory Smoke and Pneumonia in Sauda

Some fifteen years ago Sauda, on the west coast of Norway, was noted for its salubrious qualities in spite of a heavy annual rainfall. But ever since electrical smelting of certain ores, some containing manganese, converted this rural community to an industrial town, pneumonia has been disturbingly frequent and characterized by a mortality of over 35 per cent. The general mortality of Sauda is still somewhat lower than that of Norway as a whole, thanks to the recent influx into Sauda of many young adults. But the morbidity from pneumonia is four times greater and the mortality eight times greater than in the rest of Norway. It has been calculated that between the ages of 15 and 29 the mortality from croupous pneumonia over a period of several years in Sauda is 22 per 10,000 living souls, whereas it is only 1 in Oslo and only 1 in the country taken as a whole. During the past fourteen years nearly one third of all the deaths in Sauda have been due to croupous pneumonia.

In 1928 the late Prof. Axel Holst conducted an inquiry into this mystery. Even then the manganese-containing smoke from the smelting furnaces was suspected, but the results of his observations were in conflict with this suspicion and he gave an open verdict as to the solution of the problem. In the autumn of 1929 his son, Dr. P. M. Holst, instituted prophylactic injections every autumn of a vaccine prepared from pneumococci obtained from local cases of pneumonia. But the results were disappointing. Between 1934 and 1937 Dr. Dagfinn Elstad sought to determine the part, if any, played by manganese in the persistence of a high pneumonia rate. Since the summer of 1938 Dr. Riddervold has conducted tests among both patients and healthy persons with a view to determining the types of pneumococci prevalent in the community. Now, in 1939, the evidence collected by Dr. Elstad seems to point to manganese as the chief offender, the more so because the production of manganese alloys from year to year since 1930 has followed a curve remarkably similar to those of the morbidity and mortality from pneumonia.

Meeting of Tuberculosis Specialists

Scandinavian tuberculosis specialists met this summer at Trondheim, where some 125 doctors took part in a discussion on the two main subjects on the agenda: (1) the relation between the primary infection and destructive pulmonary tuberculosis, and (2) the indications for thoracoplastic operations. With the genesis of pulmonary tuberculosis once more in the melting pot, it was not surprising that disagreement had to be noted with regard to the first item. Dr. Heimbeck, the president, voiced the opinions of the Norwegian school, which teaches that pulmonary tuberculosis usually begins with large, nonapical infiltrations. The Swedish school, represented by Dr. Malmros and Dr. Hedvall, attaches more importance to small, apical, initial foci as the beginnings of pulmonary tuberculosis. The other main subject, thoracoplastic operations, found the specialists less widely divided. From the Vardaaen Sanatorium, Norway, came a report to the effect that tubercle bacilli had been banished from the sputum and cavities had been closed in 76 per cent of the cases in which operation was performed. Attention was drawn to the superiority of the immediate results obtained with sanatorium patients over the immediate results obtained with patients operated on. Did this comparison, so

unfavorable to the surgical hospital, reveal defects in the after-treatment of patients handicapped by the atmosphere of a surgical ward?

Opinions at this meeting on Calmette's BCG vaccine were remarkably favorable. A Swede, Dr. Andersson, of Gothenburg, reported briefly on a follow-up examination of about 1,000 children who between 1927 and 1937 had been given prophylactic treatment with BCG. Not one of them was found to be suffering from tuberculosis. There was general agreement at the meeting as to the considerable, if not absolute, protection conferred on tuberculin-negative reactors by BCG vaccination, and approval was expressed of the suggestion that persons found to be tuberculin negative at and after puberty should be treated with BCG.

The Norwegian Red Cross

These are stirring days. Norway is not fighting in the war but it is already involved. Its merchant fleet, so large in proportion to the population of the country, must choose between starvation at home and great risks of sinking at sea. The choice was made unequivocally within a few days of the outbreak of war between Great Britain and Germany when the Norwegian Federation of Seamen issued a statement to the effect that the Norwegian seaman means to go to sea whatever happens. He will do so the more happily for the knowledge that at home every possible precaution is now being taken to ensure the safety of the country.

Colonel Meinich, president of the Norwegian Red Cross, on August 22 gave an address on the wireless about the Red Cross and the Geneva convention. Speaking in connection with the seventy-five year jubilee of the first Geneva convention, he reminded the public of the part the Red Cross has played and will continue to play in time of war. In the autumn of 1938, when war had seemed near, the Norwegian Red Cross issued an appeal for 1,886 men and women to volunteer for air raid precaution work. The response has been such that 1,097 men and 457 women have undergone the necessary training and are ready for service. The headquarters of the Red Cross in Oslo has issued instructions to every chapter to have in readiness a complete mobilization scheme, a copy of which is to be sent to headquarters. Such a mobilization scheme comes under two headings according as it deals with personnel or material. It may be noted in passing that through the League of Red Cross Societies (with its office in Paris), of which the Norwegian Red Cross is a member and Mr. Norman H. Davis is chairman, the Norwegian and American Red Cross societies are in touch with each other.

Marriages

CARL SCOTT LINGAMFELTER JR., Dumbarton, Va., to Miss Marguerite Mae Clarke of Richmond, August 5.

LEONHARD W. LEVISOHN, Cimarron, N. M., to Miss Edith Blumenthal of New York in Denver, June 4.

FREDERICK LOUIS LANDAU JR., Bronxville, N. Y., to Miss Hattie Belle Simons at Riverdale, June 17.

FREDERICK E. KOLB, Lake Linden, Mich., to Miss Lucile Plekenpol at Cedar Grove, Wis., July 1.

EDWARD E. HADDOCK, Richmond, Va., to Miss Katherine Lois Scott of Red Wing, Minn., July 31.

MATTHEW G. SANDERS, Fort Dodge, Iowa, to Miss Cecelia Maloney of Chicago, June 24.

RUSSELL L. LAYMON, Miami, Fla., to Miss Marjorie Rich in Washington, D. C., July 7.

CLIFFORD RIGBY, Rexbury, Idaho, to Miss Wilma Murley of Tacoma, Wash., July 6.

ERNEST F. GETTO, Du Bois, Pa., to Miss Olga Gagliardi of Jeannette, July 24.

OTIS H. LAW, Pontiac, Ill., to Miss Sue Field of Miami, Fla., May 14.

Deaths

Reginald Henry Jackson ☉ Madison, Wis.; Columbia University College of Physicians and Surgeons, New York, 1899; past president of the Medical Society of the State of Wisconsin; member and past president of the Western Surgical Association; member of the Southern Surgical Association; fellow of the American College of Surgeons; surgical preceptor, University of Wisconsin, 1914-1924, and clinical professor of surgery, 1924-1928; chief of staff, Methodist Episcopal Hospital; founder in 1912 and chief of staff of the Jackson Clinic; aged 63; died, September 7, at his summer home at Breese Point on Lake Mendota of coronary occlusion.

Samuel Calvin Smith ☉ Philadelphia; Jefferson Medical College of Philadelphia, 1905; fellow of the American College of Physicians; instructor in medicine at his alma mater, 1920-1922; served during the World War; consulting cardiologist to the Misericordia Hospital, 1925-1930, and the Chester County Hospital, West Chester; on the staff of the Veterans Administration Facility, Coatesville, 1931-1932; in 1928 was awarded the honorary degree of doctor of science from Bucknell College; aged 58; died, July 31, in the General Hospital, East Stroudsburg, Pa., of injuries received in an automobile accident.

Buckner Magill Randolph, Warrenton, Va.; Medical College of Virginia, Richmond, 1898; professor emeritus of clinical medicine at the George Washington University School of Medicine, Washington, D. C., clinical professor of medicine and director of clinics from 1922 to 1930, professor of materia medica and therapeutics, 1909-1922; chief of medical service of the Walter Reed General Hospital, 1917-1919; aged 67; died, July 1, at the Veterans Administration Facility, Washington, D. C.

Isaac Ernest Greenberg, Rockaway Beach, N. Y.; Long Island College Hospital, Brooklyn, 1916; member of the Medical Society of the State of New York; served during the World War; served at various times and in various capacities on the staffs of the Rockaway Beach (N. Y.) Hospital, Queens General Hospital, Jamaica, St. Joseph's Hospital, Far Rockaway, and the Long Beach Hospital, Long Beach; aged 47; died, July 22, of carcinoma of the rectum.

Mary Priestley Sheriff Rupert ☉ Bala-Cynwyd, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1904; formerly demonstrator of medicine at her alma mater, clinical professor of medicine and lecturer in nutrition and dietetics and founder of the laboratory of clinical pathology; fellow of the American College of Physicians; aged 59; died suddenly, July 21, in Portland, Maine, of cerebral hemorrhage.

Roy Groesbeck ☉ Salt Lake City; Western Reserve University School of Medicine, Cleveland, 1913; formerly member of the city board of health; lecturer in surgery at the University of Utah School of Medicine, 1917-1919, and since 1918 examining physician in the department of physical education; on the staff of the Dr. W. H. Groves Latter Day Saints Hospital; aged 50; died, July 5, of coronary occlusion.

Ellis S. Montgomery, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1890; member of the Medical Society of the State of Pennsylvania; past president of the Allegheny County Medical Society; fellow of the American College of Surgeons; formerly surgeon to the Baltimore and Ohio Railroad; aged 79; on the staff of the Passavant Hospital, where he died, July 12.

Joseph Thomas Welch, Long Branch, N. J.; Dartmouth Medical School, Hanover, N. H., 1893; veteran of the Spanish-American and World wars; past president of the board of health and a member of the board of education; on the staffs of the Royal Pines Hospital, Pinewald, N. J., and the E. C. Hazard Hospital; aged 72; died, July 23, of carcinoma of the breast.

Alfred Milton Mead ☉ Victor, N. Y.; University of Buffalo School of Medicine, 1880; past president of the Ontario County Medical Society; for many years town and village health officer; past president of the board of education; aged 82; for many years on the staff of the Frederick Ferris Thompson Hospital, Canandaigua, where he died, July 3.

Fred Dan Vickers, Deming, N. M.; Albany (N. Y.) Medical College, 1893; member and past president of the New Mexico Medical Society; at one time coroner of Montgomery County, N. Y.; past president of the Medical and Surgical Association of the Southwest; formerly on the staff of the Deming Ladies' Hospital; aged 71; died, July 27.

Dozier Henry Gibbs * Los Angeles; Vanderbilt University School of Medicine, Nashville, Tenn., 1917; member of the American Urological Association; fellow of the American College of Surgeons; on the staffs of the Hospital of the Good Samaritan and the Children's Hospital; served during the World War; aged 43; died, July 10.

James William Ward, San Francisco; New York Homeopathic Medical College, New York, 1883; fellow of the American College of Surgeons; past president of the city board of health; formerly dean and professor of gynecology at the Hahnemann Medical College of the Pacific; aged 78; died, July 12, of coronary occlusion.

Austin Maurice Curtis, Washington, D. C.; Northwestern University Medical School, Chicago, 1891; professor of surgery, Howard University College of Medicine; past president of the National Medical Association; served in various capacities on the staff of the Freedmen's Hospital; aged 71; died, July 14, of cerebral hemorrhage.

William Walter Cross * Oakland, Calif.; Washington University School of Medicine, St. Louis, 1897; member of the American Urological Association; on the staffs of the Alta Bates Hospital and Berkeley General Hospital, Berkeley, and the Peralta Hospital; aged 66; died, July 12.

Thomas Stewart Dickson, Houlton, Maine; Bellevue Hospital Medical College, New York, 1893; member of the Maine Medical Association; past president of the Aroostook County Medical Society; medical director of the Aroostook Hospital; aged 71; died, July 13, of uremia.

John Francis Sagarino * Hartford, Conn.; Columbia University College of Physicians and Surgeons, New York, 1913; fellow of the American College of Surgeons; served during the World War; on the staff of St. Francis Hospital; aged 50; died, July 21, of cerebral hemorrhage.

Augustus Savage Lowsley, Flushing, N. Y.; Medical College of Virginia, Richmond, 1917; surgeon emeritus on the staff of the Flushing Hospital; aged 53; died, July 17, in the Community Hospital, Long Beach, following an operation for a ruptured appendix.

Walter Allen Hodges * Pasadena, Calif.; St. Louis University School of Medicine, 1905; served during the World War; medical director and superintendent of the LaVina (Calif.) Sanatorium; aged 57; died, July 22, of cerebral hemorrhage.

Augustin Aloysius Wolfe, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1894; member of the Medical Society of the State of New York; aged 77; died, July 10, of chronic myocarditis.

Charles Derastus Thomas * Peoria, Ill.; Rush Medical College, Chicago, 1888; fellow of the American College of Surgeons; on the staff of the Proctor Hospital; trustee of Bradley College; aged 75; died, July 18, of myocarditis.

Jenner Perry Chance, Carmel, Calif.; Minneapolis College of Physicians and Surgeons, 1900; veteran of the Spanish-American and World wars; aged 68; died, July 3, in the Veterans Administration Facility, West Los Angeles.

Chester Harold McCallum, Erie, Pa.; Jefferson Medical College of Philadelphia, 1905; member of the Medical Society of the State of Pennsylvania; aged 58; on the staff of St. Vincent's Hospital, where he died, July 15, of pneumonia.

Perry McDowell Tibbins, Beech Creek, Pa.; Jefferson Medical College of Philadelphia, 1905; member of the Medical Society of the State of Pennsylvania; bank president; aged 58; died, July 29, of peritonitis following appendicitis.

Daniel John Milton Miller, Ventnor, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1878; member of the American Pediatric Society; aged 82; died, July 6, in the Bryn Mawr (Pa.) Hospital.

Isaac Evans Nash * Port Chester, N. Y.; University and Bellevue Hospital Medical College, 1924; at one time chief of the urological service, Harlem Hospital, New York; aged 40; died, July 27, of coronary sclerosis.

James Hugh Hackett * Milwaukee; University of the City of New York Medical Department, 1894; aged 74; for many years on the staff of St. Mary's Hospital, where he died, July 23, of carcinoma of the stomach.

Alexander Thomas Leonard, San Francisco; L.R.C.P., Edinburgh, and L.R.C.S., Edinburgh, 1882; member of the California Medical Association; fellow of the American College of Surgeons; aged 81; died, July 2.

Charles Benjamin Hare, Los Angeles; Rush Medical College, Chicago, 1908; fellow of the American College of Surgeons; served during the World War; aged 66; died, July 2, of peritonitis following an operation.

William Henry Palmer, Janesville, Wis.; Chicago Medical College, 1882; fellow of the American College of Surgeons; aged 78; formerly surgeon to the Mercy Hospital, where he died, July 29, of heart disease.

Francis M. Kujawa * Buffalo; University of Buffalo School of Medicine, 1917; served during the World War; aged 46; died, July 12, in the Buffalo General Hospital of coronary occlusion and arteriosclerosis.

Bert Lynn Savitz * Shanksville, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1931; aged 33; died, July 12, in the Somerset (Pa.) Community Hospital of embolism and pneumonia.

Eugene Ernest Simpson, Shreveport, La.; University of Louisville (Ky.) Medical Department, 1896; aged 68; died, July 7, at Rochester, Minn., of laceration of the jugular vein, self inflicted.

Lenore Leeds Doughty, Cincinnati; Miami Medical College, Cincinnati, 1906; aged 56; died, July 5, in the General Hospital, Saranac Lake, N. Y., of spontaneous subarachnoid hemorrhage.

James Wesley Harper, Pittsburgh; Medico-Chirurgical College of Philadelphia, 1910; member of the Medical Society of the State of Pennsylvania; aged 53; died, July 19, of coronary occlusion.

Emmet Leo Reilly, Pittston, Pa.; Temple University School of Medicine, Philadelphia, 1937; on the staff of the Pittston Hospital; aged 27; was killed, July 25, in an automobile accident.

William Staughton Snow, Middletown, Ohio; Pulte Medical College, Cincinnati, 1896; member of the Ohio State Medical Association; aged 66; died, July 28, of cerebral hemorrhage.

Ray Nelson Lewis, Apollo, Pa.; University of Louisville (Ky.) Medical Department, 1909; served during the World War; aged 63; died, July 16, of a self-inflicted bullet wound.

William Henry Whitehead, Austell, Ga.; University of the City of New York Medical Department, 1876; aged 83; died, July 10, of uremia and chronic nephritis.

Robert Lee Kimmins, Meridian, Texas; Missouri Medical College, St. Louis, 1887; at one time physician to the city schools of Beaumont; aged 72; died in July.

Adolf Natzler * Los Angeles; Ludwig-Maximilians-Universität Medizinische Fakultät, Munich, Bavaria, Germany, 1907; aged 56; died, July 4.

James Robert Norrel, Indianapolis; Cleveland College of Physicians and Surgeons, 1898; aged 64; died, July 20, of bronchopneumonia.

George Hector Craig, Broadview, Sask., Canada; Manitoba Medical College, Winnipeg, 1905; aged 63; died, July 18, of coronary sclerosis.

George W. Smith, Peoria, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1887; aged 76; died, July 13, of pneumonia.

Knute Olai E. Heimark * Duluth, Minn. (licensed in Minnesota in 1899); aged 65; died, July 17, of bronchopneumonia.

Thomas William Wilson, Moscow, Pa.; Eclectic Medical Institute, Cincinnati, 1895; aged 66; died, July 31, of heart disease.

Jasper S. Stone, Healdsburg, Calif.; Medical College of Ohio, Cincinnati, 1873; Civil War veteran; aged 92; died, July 4.

James B. Clay, Dyersburg, Tenn.; Meharry Medical College, Nashville, 1900; aged 68; died, July 25, of diabetes mellitus.

Ephraim George Hughes * Long Beach, Calif.; Jefferson Medical College of Philadelphia, 1907; aged 59; died, July 7.

Zachary Fuller, Bandera, Texas; State University of Iowa College of Medicine, Iowa City, 1876; aged 85; died in July.

George Roy Galloway, Avery, Okla.; University Medical College of Kansas City, Mo., 1896; aged 67; died, July 4.

CORRECTION

Dr. Shaw Not Dead.—Dr. George Flanagan Shaw of Toronto, Ont., whose death was reported in THE JOURNAL September 2, page 959, is not dead. His death was erroneously reported by the College of Physicians and Surgeons of Ontario.

"THYOGLAND TABLETS"

Thyrex Tablets (for Toxic Goitre)

Sodium Bicarbonate	0.05	Gm.
Sodium Arsenate	0.001	Gm.
Sodium Phosphate	0.12	Gm.
Salol	0.10	Gm.
Sodium Bromide	0.05	Gm.
Calcium Oxalate	0.05	Gm."

"THYOGLAND TABLETS"

Glandex Tablets (for Toxic Goitre)

Pituitary Gland (desiccated)	0.05	Gm.
Suprarenal Gland (desiccated) USP.....	0.05	Gm.
Pancreas (desiccated)	0.05	Gm.
Corpora Lutea (desiccated)	0.05	Gm."

One tablet of this and one Thyrex tablet were to be taken together before meals.

At the hearing of the Carver case the Post Office presented scientific evidence which showed that goiter cases are divided between toxic and nontoxic and that there are many cases of swelling of the neck in the region of the thyroid gland which the layman might easily mistake for goiter even though they had no relation to it; and, further, that the information furnished by those who filled out the question blank would not enable even a physician properly to diagnose the case and prescribe the necessary treatment in all types of goiter. In addition, the expert testimony brought out that in certain types of toxic thyroid the administration of Carver's treatment would be dangerous, in spite of the promoter's claims to its being "a safe remedy"; that it might change a case of simple goiter to one of a toxic or dangerous type, and that, where there are changes in the tissue of the thyroid gland due to the disease of hyperplasia extending over a long period of time, the condition would not respond to any medical treatment.

The Solicitor, in commenting on Carver's claim that his offer to refund the price of the treatment to dissatisfied users eliminated the possibility of fraud, pointed out that this same contention is made by the promoters of practically all fraudulent mail order schemes, and that the customer, even should he succeed in getting his money back, has nevertheless been defrauded in having been given false hopes; and, further, that in some cases the customer may not discover he has been swindled and so may not seek a refund.

Carver, while admitting he was not qualified as a physician, claimed he had read a number of books on goiter and had been associated with certain physicians during the operation of his business. He presented several affidavits from physicians in which it was stated that they had used the Thyogland Treatment in goiter cases and that it was their opinion, based on this experience, that the thing would have some value in goiter. Carver admitted he had written these affidavits himself and then got the physicians to sign them.

For these and other reasons the Solicitor recommended to the Postmaster General that a fraud order be brought against Lyell Carver, and it was issued on Sept. 24, 1938. It now remains to be seen whether Carver will again bob up in the field of mail order quackery operating under a new trade style and exploiting a new "cure."

In closing it may be worth mentioning that a list of complaints ordered by the Federal Trade Commission from June 10, 1929, to April 15, 1930, against certain concerns and individuals for making false claims for their respective wares included the name of Lyell C. Carver.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Happy Day Headache Powders.—Gulf Laboratories Co., Inc., Lafayette, La. Composition: In each powder, approximately 2.4 grains of acetanilid, 3.2 grains of aspirin, 0.4 grain of caffeine, and 0.2 grain of phenolphthalein, with milk sugar and citric acid. Fraudulent therapeutic claims.—[N. J. 28707; November 1938.]

National Pain Relief.—National Medicine Co., Nashville, Tenn. Composition: Essentially extracts of plant drugs including red pepper and ginger, a small amount of an ammonium compound, camphor, chloroform, alcohol (4.2 per cent by volume), glycerin and water. Fraudulently represented as a remedy for dysentery, diarrhea, fluttering of heart, shortness of breath, etc.—[N. J. 28988; November 1938.]

Seeqit.—Seeqit & Tiques, Inc., New York. Composition: Tablets each containing about $4\frac{3}{4}$ grains of aminopyrine and $\frac{3}{8}$ grain of caffeine. Fraudulently represented as a harmless remedy for menstrual discomforts and as a product endorsed by many physicians.—[N. J. 28679; November 1938.]

Correspondence**DISTURBANCES OF THE PENDULAR
MOVEMENT OF THE ARM
IN WALKING**

To the Editor:—A short time ago Robert Wartenberg (A Cerebellar Sign, THE JOURNAL, April 15, p. 1454) reported his observations on the decrease or cessation of the arm-swinging movement in walking in cases of homolateral disease of one of the cerebellar hemispheres. After considering similar observations by Holmes, Thomas, Marburg, Dusser de Barenne and others, Wartenberg designated this phenomenon as "cerebellar sign" and concluded his discussion by saying that "it would be of interest to study the swinging movement of the arm in unilateral frontal disease." I had occasion to observe this phenomenon in two cases of unilateral injury of the frontal brain:

1. A man aged 42 was wounded in the left side of the forehead by a shell splinter in 1916. Examination in 1932 revealed in the middle of the left side of the forehead a scar with a bone defect covering the middle of the first and second convolutions of the left lobe of the frontal brain. The patient showed signs of disturbance of frontal equilibrium on the contralateral side, such as past pointing with the right arm, rocking and falling to the right and, besides, a contralateral deviation in going forward and a homolateral deviation in going backward. In this case, in which no other disturbances of the pyramidal motor or the sensory system were manifested, the swinging movements of the contralateral arm in walking were markedly reduced in comparison with the other arm.

2. A man aged 44 had been similarly wounded in 1917 by a shrapnel bullet in the left side of the forehead above the eyebrow. On examination in 1932 a scar 7 cm. long and 4 cm. wide was found on the left frontal bone going obliquely upward from the lateral corner of the eye and gradually narrowing toward both ends. The bone defect corresponded to the second and third convolutions of the frontal brain. This patient presented, besides the sign of heterolateral disturbance of frontal equilibrium similar to that of the first patient, a habitual bending of the head to the right shoulder and an automatic resumption of this attitude on passive change of the position of the head. Along with an otherwise entirely intact motor and sensory system he manifested a complete loss of the swinging movement of the contralateral arm in walking.

Both of these cases, which were discussed at greater length in connection with their bearing on the phenomenon of question (Halpern, L.: On the Disturbances of the Pendular Movement of the Arm in Walking, Harefuah 7:ii [May-June] 1933) and on the problem of the relation of the frontal brain to equilibrium (Halpern, L.: Ueber das Symptomenbild der Stirnhirnläsion unter spezieller Berücksichtigung der Störungen des Gleichgewichts, Monatschr. f. Psychiat. u. Neurol. 94:13 [Sept.] 1936), indicate (a) that disturbances of the swinging movement of the arm do occur also in cases of involvement of the frontal brain and (b) that in cases of unilateral injury

of the frontal brain this disturbance is manifested in the swinging movement of the contralateral arm in walking.

A comparison of my observations with those of Wartenberg indicates further that the disturbance of the swinging movements of the arm is not of pathognomonic significance for the cerebellum but constitutes a symptom of disturbance in walking which is manifested homolaterally or contralaterally according to whether the cerebellum or the frontal brain is involved. Finally, these observations prove that frontocerebellar cooperation covers not only the regulation of static equilibrium but the balancing of the body in walking and certainly the performance of walking in general.

STANDARDIZATION OF BLOOD PRESSURE READINGS

To the Editor:—The special article on this subject in *THE JOURNAL* July 22 induces me to emphasize paragraph 5. Equal and not excessive pressure should be made by the bell of the stethoscope in taking the blood pressure. Particularly in children, and occasionally in adults in whom the blood pressure is low, especially when the diastolic blood pressure is low, it is necessary to place the bell of the stethoscope in such a manner that the entire ring of pressure is equal and that the upper ring of the bell does not press harder than the lower. If the upper half of the ring of the pressing bell of the stethoscope should be pressed harder, the pulse beat will continue to be heard long after the true diastolic point has been reached. The extra pressure of the bell of the stethoscope acts in the same manner as if there were an increase of pressure in the cuff. The pulse beat can also be heard without the cuff by pressing the upper segment of the stethoscope bell or diaphragm on the artery.

The interpretation of the Korotkow sounds of auscultatory blood pressure estimation may be simply explained in the following manner: The radial pulse is felt because it strikes the obstructing finger just as the vibration of a board held in the hand can be felt when struck by a wave or by a fist. Similarly the sound of the blow can be heard. When the cuff is pumped up tightly to beyond the systolic blood pressure, the artery beneath the cuff is completely compressed and the pulse wave is stopped at the upper end of the cuff. No pulse can be felt nor sound heard in the antecubital space because the muscle does not transmit sound well, certainly not at the 12 cm. distance of the cuff. When the pressure is released sufficiently so as to permit the blood stream to carry and transmit the sound created by the pulse wave striking the obstruction, i. e. the partially compressed artery, one can hear the sound (Korotkow) or feel the pulse. This transmitted sound of the pulse wave striking the obstruction is heard until there is no more obstruction. This occurs when the pressure in the cuff is about equal to that in the artery. There being no obstruction, the pulse wave continues uninterrupted and no vibrating element is in the way. The point at which the sound disappears should be considered the diastolic pressure.

From this simple exposition of the cause of Korotkow sounds, one can see that excessive pressure of the upper segment of the bell of the stethoscope can be the means of producing sounds at the antecubital fossa, as may other obstructions either within or without the artery.

E. I. FOGEL, M.D., Cincinnati.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HYPERGLYCEMIA AND DIABETES

To the Editor:—1. Why is it desirable, if it is desirable, to maintain a normal blood sugar level other than to prevent ketosis in the treatment of diabetes? 2. (a) What harm can result (when ketosis is omitted) from a persistent hyperglycemia in a diabetic subject and what is the mechanism that brings this about? (b) How is the relationship between hyperglycemia of diabetes and the complication of diabetes proved (when ketosis is omitted)? 3. What should be the objectives in the treatment of diabetes in the aged and in those who are not aged?

M.D., New York.

ANSWER:—1. Normal blood sugar values are obviously the best. In diabetes a normal percentage of sugar in the blood, as a rule, indicates a blood normal in other respects as well. Thus far, no one has ever reported a series of 100 or more cases of diabetes with known hyperglycemia for ten years in which there has been freedom or even relative freedom from serious complications of diabetes or, indeed, freedom from evidence of progression in the diabetes as manifested by loss of weight, strength and ambition. Irrespective of the different ideas regarding dietetic treatment, there has been in the past unanimous agreement in the insistence on aggressive measures to attain normal values for blood and urine.

2. (a) Persistent hyperglycemia implies persistent glycosuria, except in the few cases in which there is a high renal threshold. Hyperglycemia and glycosuria involve accessory annoyances such as polydipsia and polyuria, the attendant necessity for extra food to make up for the loss of calories in the urine and the obvious wear and tear on the system for ingestion, assimilation and excretion of this unutilized extra food.

Hyperglycemia is a constant stimulus to the islands of Langerhans of a pancreas already impaired and overburdened. It allows no time for recuperation such as the pancreas of a healthy person enjoys between meals and at night.

Such patients are less resistant to infections even though the mechanism is not surely demonstrable by bacteriologic tests.

They acquire more complications than diabetic patients who are controlled.

Diabetes is not static and Naunyn's dictum still holds that many a case originally was mild but neglected.

Statistically, the duration of life in cases of uncontrolled diabetes is shorter than in cases of controlled diabetes.

If hyperglycemia is allowed, one yardstick is lost by which to measure the status of the patient. There are variables enough in the management of diabetes without the addition of high blood sugar of uncertain degree throughout the day.

(b) It is not proved directly, but there is no more reason for disregarding this signal of something being wrong than to fail to stop at a red light at a railroad crossing because one cannot see the train around the corner. It is granted that one may not be able to explain by laboratory methods that the person with uncontrolled diabetes has a lowered resistance to bacteria, but the great frequency of infections in diabetic patients with hyperglycemia is acknowledged. No one claims that hyperglycemia is responsible for all the complications of diabetes. Diabetes is a deficiency disease, and when the condition is brought under control by a correct adjustment of diet and insulin (either endogenous or injected) the occurrence of diabetic complications becomes rare.

3. The objectives in the treatment of diabetes are the maintenance of comfort, vigor, a reasonable weight within the normal zone or slightly below, and control of glycemia and glycosuria, although all agree that chemical meticulousness is to be avoided to prevent the exposure of the patient to hypoglycemic reactions.

The same rules hold for old and young relatively. Thus, if complete control of carbohydrate utilization is sought, it is obvious that the total dextrose excreted in the young will be considerably more than that in the old because of the larger diets of youth.

HEMIPLEGIA FROM CONTRALATERAL VASCULAR
ACCIDENT

To the Editor:—A man aged 54, short, stocky and overweight, had a tension averaging 150 systolic and 90 diastolic prior to onset of the following: An attack of influenza lasting one week left the patient weak for several weeks. The blood pressure at this time rose no higher than it had previously. From two to three weeks after the "flu," according to the history, the patient began to complain of some difficulty in speaking, and occasionally he broke out with crying spells. Later the patient became highly excitable, cried freely and complained of speech difficulty and weakness of the right arm and hand. Examination revealed a blood pressure of 210 systolic, 100 diastolic, weakness of the hand grasp on the right side, absence of the abdominal reflex on the right side and a suggestive Babinski sign elicited by the right foot. Diagnosis at the time was possible cerebral thrombosis affecting the left middle cerebral artery or its branches, possible angiospasm or a frank hemorrhage of a smaller vessel. The only significant laboratory work revealed a mild diabetic condition, later verified by repeated chemical analyses of the blood, urinalyses and the like. Diet, medication and rest in the course of time helped bring about an apparent "cure," with this exception: The right arm and especially the hand is swollen, edematous and painful to such an extent that the patient is unable to use this member. Pain at the shoulder is complained of. Various physical therapeutic measures at first seem to reduce the swelling but with recurrence. I am at a loss to explain this phenomenon unless he may have a thrombosis of the right axillary vein. Any suggestions will be appreciated. Henry Rosner, M.D., Brooklyn.

ANSWER:—The manifestations of right-sided hemiplegia with spasticity in a diabetic patient aged 54 certainly speak for a contralateral vascular accident in the brain. The finding of a painful edema of the hemiplegic extremity without any venous obstruction is not uncommon. The insufficient venous return may be explained by diminished muscular activity and the increased vasodilation in the hemiplegic limb. It is possible, however, that an axillary thrombosis followed the venous stasis, but in that case a palpable cord in the axilla or marked increase in the size of the cutaneous veins around the shoulder and the anterior wall of the chest should be found. The injection of an opaque substance such as skiodan or diodrast into the cubital vein followed by the taking of an x-ray film readily demonstrates the patency or block of the axillary vein.

Elevation of the edematous limb on pillows together with the administration of a mercurial diuretic, such as salyrgan or mercupurin, helps to empty the arm of the excessive fluid. The pain in such extremities is usually considered to be thalamic; mild sedatives hardly influence it. Repeated injections of procaine hydrochloride into the stellate ganglion may help to relieve both the edema and the pain.

CHAULMOOGRA OIL AND TUBERCULOSIS

To the Editor:—I should like information regarding the use of chaulmoogra oil in tuberculous infections of the bronchi, trachea, larynx, pharynx or nose, whether by application or inhalation of spray. What strength is used and with what frequency? What type of the oil or similar substances or derivatives from these are used? What toxic effect are to be avoided and how? What results are to be expected?

M.D., Pennsylvania.

ANSWER:—Chaulmoogra oil has been found to have approximately a hundred times the bactericidal effect found in phenol, as far as the acid-fast bacteria are concerned. The active principle of chaulmoogra oil is in its acids, which inhibit the proliferation of the leprosy bacillus and the tubercle bacillus.

In treating tuberculosis the ethyl esters were at one time administered in doses of 3 cc. by mouth. However, patients did not tolerate this treatment well and the substance was then administered intramuscularly. This often resulted in intense pain, induration and inflammation at the site of injection. It was next administered intravenously with an initial dose of 1 cc. once a week, and later the intervals were increased to from two to four weeks.

Various methods of local application were also employed. For example, Bronfin and Markel treated fifty cases of tuberculous laryngitis with local applications of chaulmoogra oil and the ethyl esters of the oil. Their observations extended over a period of from ten to twelve months. The two forms of the drug were used in different cases and were administered intratracheally beginning with 5, 10, 25 and 50 per cent of the drug mixed with pure liquid petrolatum. The authors were unable to note any difference in action of the two forms. They did not observe an aggravation of symptoms, as had been reported by some authors, or an improvement, as other authors had reported. However, they did notice an increase in the local ulceration in some cases, which they believed was due to the irritating effects of the drug. In no case was there observed a decrease in the cough or sputum. Apparently the only possible effect that chaulmoogra oil could have would be a germicidal action on the tubercle bacilli that have been set free and lodged on the lining

of the bronchi, trachea, larynx, pharynx or nose. This is of no significance as far as the actual disease in these parts is concerned, however, since the preparation does not reach the depths of the lesions.

Unfortunately, there is no proof available that chaulmoogra oil has any beneficial effect in the treatment of tuberculosis in any form. Moreover, it has been shown that chaulmoogric acid does not penetrate tubercle. Therefore, chaulmoogra oil has been almost entirely abandoned in the treatment of tuberculosis.

POTENTIAL HERNIATION

To the Editor:—In examining men for employment I have been considering a bulging through the inguinal canal on effort as a hernia. I consider such as an incomplete hernia and in executing a waiver just put down "rupture." Am I wrong in making such a diagnosis? No one seems to agree with me that a hernia exists. Will you settle this matter for me? I do not wish to do an injustice to any man and want to be fair with both employee and employer. M.D., Connecticut.

ANSWER:—A bulging in the inguinal canal is frequently spoken of as a bubonocoele. The term is confusing rather than helpful. Conditions of this nature are often called "potential hernias." All men have potential hernias. In 33 per cent a bulging high up in the inguinal canal can usually be detected.

Conditions of this kind are generally symptomless, and unless a palpable mass protrudes beyond the fascial pillars forming the external opening of the inguinal canal they should not be considered as being "ruptures." When there is a persistence of symptoms, operation is sometimes recommended. Rarely a small cyst may be found within the inguinal canal, and frequently a large pedunculated pad of properitoneal fat is responsible for the symptoms. In industrial work, for a symptomless bulging which does not extend beyond the inguinal canal what is sometimes spoken of as a "prophylactic herniotomy" is not recommended. If instructions were given to the men to keep the legs together when doing heavy lifting and avoid awkward positions, a large number of industrial hernias probably would be avoided.

In inguinal hernias of the direct type it is more difficult to determine when an abdominal weakness actually becomes a hernia unless there is an area of bulging which can be seen as well as felt, particularly in comparison with the unaffected side. These conditions are not usually considered as being a definite herniation and it is believed that such men should not be rejected for employment.

OBSTETRIC DEATHS

To the Editor:—What in your opinion constitutes an excusable obstetric death? Of course I realize that those instances of violence or other conditions which place the case in the medical examiner's jurisdiction must be excluded from the list. M.D., New York.

ANSWER:—In assessing the responsibilities for obstetric death, many different factors must be considered: first, the patient; second, the attendant, usually a physician, and third the institution or home conditions and undeterminable factors. If, for instance, the patient neglected to report to a physician or, after having reported, neglected to follow his instructions relative to the proper care of herself, as in eclampsia, one would say that that was an excusable death from the standpoint of the physician but not from that of the patient. In other words the death would be assessed to the patient and not to the physician. If, on the other hand, the patient followed the physician's advice and died from eclampsia and it was decided that the treatment was not adequate, the death would be assigned to the physician.

If the patient died from infection acquired during confinement, and improper or inadequate technic was used, it would be considered an inexcusable death. If, on the other hand, all proper precautions were taken and the patient died from sepsis, it would be an excusable death and the physician would not be charged with it. It would probably be assigned to undeterminable causes. If a patient enters an institution and dies from hemorrhage, and proper equipment is not available nor prompt and adequate treatment of the hemorrhage, the death would be assigned to the institution. If on the other hand, all facilities were available and used and the patient died, it

would be considered an excusable death, especially if the patient was admitted in a moribund condition not having been under the care of a physician or not entering the institution in time to afford proper opportunity for therapeutic measures.

An excusable death from the standpoint of obstetric practice would therefore be one in which there had been proper cooperation between patient, agency and physician and in spite of intelligent and sufficient treatment being used death occurred. It is difficult to define excusable in general terms, since each case must be properly evaluated and considered on its merits in connection with the environment and the circumstances involved.

TONSILLECTOMY VERSUS ELECTROCOAGULATION

To the Editor:—Please tell me the modern attitude on the problem of the surgical removal of tonsils versus the removal by electrocoagulation.

M.D., Connecticut.

ANSWER.—It is fair to say that the best opinion today favors the surgical removal of tonsils. There are times when electrocoagulation is useful, particularly in the aged and the debilitated and when small remnants are to be removed. The reason electrocoagulation is not used oftener is probably that it requires numerous sessions and that it is exceedingly difficult to tell when one has done too much or too little. Bleeding may occur just as it does following surgical removal, and this bleeding is more often of an obstinate type and starts as long as two weeks after the intervention. Lastly, there is always the possibility of an infected piece of tonsil being buried beneath a heavy scar, which may cause more trouble than the untreated tonsils did originally.

MILIARIA RUBRA OR PRICKLY HEAT

To the Editor:—Since living in south Texas, for the last two summers, I have been suffering from prickly heat (*miliaria rubra*). Remedies recommended by both medical and lay friends have been of no avail. I have tried alcohol sponging, followed by the so-called Mexican heat powder labeled to contain camphar, zinc oxide, boric acid and starch; I have used several other powders; I have bathed in water with sodium bicarbonate; I wear the lightest possible cloth; I have taken all kinds of laxatives. There has been no relief of the prickly heat, except for a short time. What is known as to the pathophysiology of *miliaria rubra*? I noticed a peculiar bitter taste of my perspiration when suffering from *miliaria*. Is it a metabolic disturbance? Can you recommend any remedies other than those mentioned, with some hope for relief? Is there any literature on the disturbance?

M.D., Texas.

ANSWER.—This query centers around the treatment of *miliaria rubra* (prickly heat), but a more intimate description of the eruption would be advisable to make sure that this diagnosis is correct. Does it occur only in the covered parts or are the exposed surfaces also affected? Is the rash accompanied by hyperhidrosis (excessive sweating)? Are there any other factors, e. g. external irritation, which may contribute to its chronicity? Perhaps another careful dermatologic examination may disclose some important points which have been overlooked.

Miliaria rubra is generally conceded to be a disorder due to occlusion of the sweat ducts, which may be due to swelling of epithelial cells unprotected by sufficient oil. There is accompanying dilatation of the capillaries and sweat ducts in the cutis, and vesicle formation may appear in the malpighian layer—the latter phenomenon is not connected with the sweat apparatus. *Miliaria* is not due to a metabolic disturbance but it may occur secondarily, in hot weather or climate, to hyperhidrosis, which may be associated with one of many general diseases, among which the metabolic must be included. If excessive sweating is evident one should search for its cause and eliminate or control it, if possible, thereby removing one important factor in the cause of *miliaria rubra*. The condition may be complicated in some persons by all varieties of eczema and intertrigo, and these must necessarily be cleared up. A *miliaria*-like eruption is known to occur as a dermatophytid secondary to a ringworm infection, perhaps of the toe webs, especially in highly sensitized persons. Occasionally contact with external irritants or the ingestion of drugs may produce a condition resembling prickly heat.

Soothing preparations are of especial value, preferably lotions and powders. Starch, almond meal or bran water may be applied and the area then dried and dusted with 10 per cent boric acid powder in equal parts of zinc oxide and starch. A thick calamine lotion with or without phenol may be tried. Sodium bicarbonate 1:200 may be used or may be incorporated in the calamine lotion. From 3 to 5 per cent solution of coal tar in calamine lotion may relieve the pruritus. An aqueous solution of aluminum chloride starting with 10 per cent and increasing, if necessary, to 25 per cent may control the perspiration.

NO SERUM FOR EPILEPSY

To the Editor:—Is there a qualified physician in Missouri who treats epilepsy with some kind of serum and supposedly gets good results? Is there any federal hospital for epileptic patients in the country? A girl aged 15 has epilepsy. The mother has heard that there is some one in or near Missouri who has had these good results. Is there any place outside of a state hospital where this girl could be adequately treated without too much expense? I shall appreciate any information that you can give me along this line.

M.D., North Dakota.

ANSWER.—No ethical, qualified physician would attempt to treat epilepsy with a serum, since there is no recognized serum treatment of this disease. All the recent medical literature on epilepsy recommends treatment with the ketogenic diet, dehydration, phenobarbital and diphenyl ethyl hydantoinate. The treatment can be effectively carried out by any qualified family physician.

There is no federal institution for the care of epileptic patients. This child would be best treated by a pediatrician or internist whom the family physician knows to be interested in epilepsy.

SCARRING AND PAIN IN JAW

To the Editor:—A patient aged 55 had a radical operative procedure performed in the left floor of the mouth for a malignant condition nine years ago. There is no evidence of recurrence, but at short intervals of about two weeks he has attacks of severe pain in the region of the lower part of the left jaw. This is made worse by swallowing. The pain is incapacitating and at times the patient becomes despondent. All forms of therapy are of little avail. The cause of the pain seems to be scar tissue, at which there is a great deal. Any therapeutic procedures will be appreciated.

Thomas Dechairo, M.D., Westmoreland, Kan.

ANSWER.—It would seem that the large amount of scar tissue in this area might well involve some nerve branches and, on swallowing, some traction might cause pain. One should also exclude a recurrence of the original growth. Spasmodic occlusion of the submaxillary duct, evidenced by an acute swelling of the submaxillary salivary gland, should also be eliminated.

Hot wet applications for an hour at a time twice a day and anodynes followed by exercise in an effort to soften the scar tissue may relieve the pain.

POISON IVY AND MILK

To the Editor:—When game farms plant poison ivy along stone walls to furnish berries for winter food for birds, it is found that farm animals destroy the crop by browsing in dry seasons. If people drink milk from cows fed on poison ivy leaves, would there be any tendency toward developing immunity after drinking such milk? Would there be less injury to the kidneys from injection of extracts as a defensive measure?

Robert T. Morris, M.D., Stamford, Conn.

ANSWER.—It is theoretically possible that the active principle of *Rhus toxicodendron* is secreted in milk. This, however, has not been demonstrated. It would be much simpler if one were to try oral immunization to give the tincture of *Rhus toxicodendron* by mouth, so that a known dose is given. This method of immunization is seldom used. Its value is questionable.

Regarding the inquiry dealing with kidney injury, it is assumed that the inquirer has in mind the possibility of such damage through the injection of therapeutic and prophylactic doses of the extract of *Rhus toxicodendron*. No such harm occurs from ordinary doses.

PAIN AND ANALGESICS

To the Editor:—A patient for the past five years has been taking daily about twenty tablets of empirin compound. I have tried to take them away from him but after a day he is wild with the pain in his head and if it is made impossible for him to get any he is semidelirious. I can find no real help in the literature I have at hand and would like advice as to the best method to use in this case.

M.D., Massachusetts.

ANSWER.—A patient suffering from such pain needs, of course, a careful diagnostic examination to determine the cause of the pain to secure its relief by remedying the cause. If it cannot be done and the pain is located in a definite peripheral nerve territory, its relief by injection of a local anesthetic should be attempted; if this is unsuccessful, injection of alcohol or, what is more permanent, nerve resection should be employed. Until the pain has been relieved by either of these means, the patient is entitled to some analgesic, and it is desirable to change the analgesic formula from time to time so as to minimize the danger of unfavorable results on the system from prolonged use of any one drug as well as to lessen the neces-

sity of increasing the dose because of habituation. Empirin compound is the non-Council accepted proprietary name of Burroughs-Wellcome & Co. for a mixture of acetylsalicylic acid $3\frac{1}{2}$ grains (0.22 Gm.), phenacetin (acetophenetidin) $2\frac{1}{2}$ grains (0.16 Gm.), and caffeine one-half grain (0.03 Gm.).

DOG BITES AND RABIES

To the Editor:—My attention has been directed to the reply that was given to Dr. Collins of Seattle concerning the treatment of bites by rabid dogs, which appeared on page 1283 of *The Journal*. As one who has had considerable experience with rabies, both human and animal, clinical and experimental, I feel that I must disagree with the opinions expressed. They are also at variance with the opinion of all authorities with which I am familiar in the matter of the value of efficient cauterization. I would like to have specific references to those who believe that cauterization is a method " . . . which was considered proper treatment in the days of Ambroise Paré but which thinking persons have abandoned just as did Paré." If the vaccination were 100 per cent effective it would be a different matter, but it is not always successful in bites destined to have a short incubation period. I have witnessed three human deaths which might have been prevented had cauterization been applied. Cauterization must always be with pure nitric acid. Phenol and iodine are not acceptable.

W. H. Kellogg, M.D., Berkeley, Calif.

To the Editor:—On page 1283 of the April 1 issue of *The Journal* the idea is put forward that dog bites should not be cauterized but should preferably be cleansed with soap and water and irrigated with a warm salt solution. It is an almost universally recognized procedure in health departments to cauterize dog bites with fuming nitric acid unless circumstances make it quite clear that there is no need to fear rabies. The health departments also recommend this procedure to all practicing physicians in their respective areas as the only approved method of preliminary treatment. Is *The Journal* taking a stand against nitric acid cauterization? If so, it is surely desirable that this question should be discussed at much greater length. Health officers are bound to have difficulty with practicing physicians over the subject of treatment at dog bites unless it is discussed with sufficient fulness so that both groups will know what stand is being taken by *The Journal* and will be made acquainted with the reasons for that stand. If the general practice of health departments is wrong, it is quite possible that they will change it, but not until there are good and sufficient reasons for doing so.

J. L. Pameroy, M.D., Los Angeles.

To the Editor:—In *The Journal* April 1, page 1283, a discussion of the indications for antirabic vaccination appeared. This discussion has certain possibilities of doing harm. A statement which I think is particularly dangerous reads as follows: "When the wound resulting from a bite is treated immediately and carefully in this fashion the administration of antirabies serum is not advocated in all instances." This sentence appears after the paragraph deploring cauterization of dog bites and recommending thorough cleansing with soap and water. This seems to me to place too much reliance on local treatment, no matter what the nature of the treatment may be. It is certainly dangerous to imply that the bite of a rabid animal should not be followed by antirabies vaccine unless specific indications are given. I myself am unacquainted with any bite of a known rabid animal resulting in a definite wound which should not be followed by antirabies vaccine. The published statement may tend to encourage careless practice with unnecessary danger to some individuals.

Ralph S. Muckenfuss, M.D., New York.

ANSWER.—Particulate matter introduced into the soft tissues is carried away rapidly by the lymphatics; in fact with such startling speed that brilliant dyes injected into the skin of the forearm can be recognized as high as the axilla in eight minutes, and injection of the lymphatics over an area several inches in diameter about the site of the inoculation takes place within as short a time as eighty seconds. These facts were graphically set forth by Hudack and McMaster in a series of papers in the *Journal of Experimental Medicine*, and an editorial calling attention to their reports appeared later in *THE JOURNAL*. It is therefore pertinent to ask whether one could hope to destroy by any local application all of a virus which had been carried into the deeper layers of skin and subcutaneous tissues when some of it is far out of reach within a few moments of the time of inoculation.

The second point is that powerful chemicals destroy tissue just as quickly and certainly as they could destroy any virus or bacterial contamination. Since it is illogical to think that all of the contaminating material could be destroyed, no matter how thorough the cauterization, because a part of it is already beyond reach of local treatment, it seems reasonable to think that the destroyed and devitalized tissue would make development of infection and increase of contamination greater instead of less. Certainly this has been demonstrated many times as far as bacterial infection is concerned. Whether the same reasoning can be applied directly to the problem of rabies is not established with certainty.

In answer to Dr. Muckenfuss's comments it should be pointed out that at no time has it been implied that a patient bitten by a rabid animal should not receive Pasteur treatment. In such an event the immediate and careful cleansing of the wound would be followed promptly by administration of antirabies vaccine.

The whole subject needs further experimental investigation.

—Ed.

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in *THE JOURNAL*, September 30, page 1353.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. *Written.* Part I. Various places throughout the United States and Canada, Feb. 15. *Oral.* Part II. Philadelphia, Oct. 14-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Oral.* Philadelphia, Nov. 3-4. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Various sections of the United States, Feb. 19. Formal application must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination and review of case histories (Part I) for Group B candidates will be held in various cities of the United States and Canada, Jan. 6. Applications for admission to Group B, Part I, examinations must be on file not later than Nov. 15. General oral and pathological examinations (Part II) for all candidates (Groups A and B) will be conducted in Atlantic City, N. J., June 8-11. Applications for admission to Group A, Part II examinations must be on file not later than March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).*

AMERICAN BOARD OF OPHTHALMOLOGY: *Written.* Various cities of the United States and Canada, March 9. *Oral.* New York, June 10. Formal applications must be received before Jan. 1. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Boston, Jan. 20-21. Applications must be filed on or before Nov. 1. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF PATHOLOGY: Memphis, Nov. 22-23. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: New York, April 30 and May 1. Kansas City, Mo., preceding the Region III meeting of the American Academy of Pediatrics. Seattle, June 2. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, December. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlanta, Ga., Dec. 9-11. Sec., Dr. Byrl R. Kirklind, 102-110 Second Avenue S.W., Rochester, Minnesota.

AMERICAN BOARD OF UROLOGY: Chicago, Feb. 9-11. (The only examination session to be held in 1940.) Case reports must be submitted not later than November 9. Sec., Dr. Gilbert J. Thomas, 1009 Nicolet Ave., Minneapolis.

North Carolina June Report

Dr. W. D. James, secretary, Board of Medical Examiners, reports the written examination held at Raleigh, June 19-23, 1939. The examination covered sixteen subjects and included eighty-four questions. A general average of 80 per cent was required to pass. Fifty-seven candidates were examined, all of whom passed. Twenty-four physicians were licensed by reciprocity and five physicians were licensed by endorsement. The following schools were represented:

Sports for the Handicapped. By George T. Stafford, Ed.D., Associate Professor of Physical Education, The University of Illinois, Urbana. Cloth. Price, \$2.75; school price, \$2. Pp. 302, with 17 illustrations. New York: Prentice-Hall, Inc., 1939.

This book aims to present to all concerned with the education of the handicapped a method of teaching that will motivate the atypical student to improve not only his physical condition but also his outlook on life. The percentage of handicapped children is large enough to warrant serious attention. Most books on sports are for the normal children. This deals with sports for the handicapped or abnormal. These recreative activities should have the following criteria: 1. The activity should have some corrective or ameliorative value for particular functional defects. 2. It should have a minimum of "expectancy of injury" or aggravation of the handicap. 3. It should have some recreative value for the individual with either functional or structural defects. The book takes up the different handicaps, such as partial handicaps, more complete disability, functional and organic heart disease, amputations, ankylosed joints, endocrine dysfunctions, debilities following long chronic illness or short acute illness, muscular deficiencies, foot defects, malnutrition, flaccid and spastic paralyses, respiratory and nasal disturbances, postural defects and spinal curvatures. The author tells the kinds of sports that these different students should take up and then goes into detail as to exactly what sports and how vigorously they should be indulged in. The book is well written and the subject thoroughly taken up. There are many illustrations. This book should be useful to those interested in or working with this class of students.

Chirurgisch-orthopädische Sportambulanz. Von Herbert Pirker, Dr. med., Leiter der Chirur. Abt. des St. Rochusspitals Wien, und H. Wunderlich, Dr. med. habil., Facharzt für Orthopädie in Leipzig. Paper. Price, 27.60 marks. Pp. 391, with 195 illustrations. Leipzig: Johann Ambrosius Barth, 1939.

The point of view and scope of this book are best brought out in the preface. Sport surgery, it indicates, is defense surgery in time of peace. A thorough training in sport surgery must be assumed as a necessity for every physician who (it matters not in what place or in what community) has a care for the cultivation and maintenance of the power of self defense among his people. For this reason sport surgery must occupy an important place wherever physicians or students wish to secure the proper knowledge required by their activities in defense situations or, in fact, by their practice in any community which has a high regard for defense preparation. The idea of the book came to expression during the surgical defense courses for physicians during the war situation in Vienna. In the darkest "illegal" times, during the winter of 1934-1935, the planning and work for this book began, and the political events of recent years in the German-Austrian territory were associated with it to the time of its completion. Foreseeing subsequent political developments, three persons came together in the late autumn of 1937: a German publisher, a Leipzig orthopedist and a Vienna surgeon. They planned this book to offer all that might be required for the practicing physician (whether he was the best situated sport physician in a city or in a popular resort or a country doctor who was compelled to make use of the most primitive resources) in the way of recognizing and treating injuries acquired during sports.

It was taken for granted that it is necessary for every practical physician to be personally concerned with the treatment of such injuries and that the idea is untenable that every more serious joint sprain requires treatment in a hospital.

The authors have tried to bring into this book all the important scientific doctrines of recent years which have offered a new biologic consideration of injuries to the apparatus of movement in such a way that they will be woven into a book with purely practical ends and will be easily grasped. Gymnastics and training sports and all therapeutics must be so treated that the reader recognizes at first glance what needs to be done. No method may be so complicated that in its application injurious passive movements may arise through unskilful handling. Yet suitable attention must be allowed to the many demands which a fully trained clinician would call for.

The authors take up in an orderly way the various methods of diagnosing and modes of treating sport injuries in general. Then they cover the different sports, with their characteristic injuries. After this the different parts of the body are considered in detail with regard to traumatic lesions common to them. The symptoms, diagnosis, prognosis, treatment and aftercare are described for many of the more important conditions.

The book is well gotten up, the printing and paper are excellent and the illustrations, including the reproductions of roentgenograms, are produced with characteristic efficiency. If there is any criticism, perhaps there are not enough details with regard to treatment.

Clinical Pathological Gynecology. By J. Thornwell Witherspoon, B.S., B.A., M.D. Cloth. Price, \$6.50. Pp. 400, with 271 illustrations. Philadelphia: Lea & Febiger, 1939.

A new textbook on gynecology added to the already crowded list! This book, although presenting the latest in ovarian tumors, is incomplete and sketchy. The author in his preface states that the book is designed for the medical student as a correlator between gynecologic pathology and clinical gynecology. For this purpose it may serve well, but even the pathology is not complete enough to give a good background. The illustrations of gross and microscopic pathologic changes are excellent, as are those showing patients with various endocrine disorders. The bibliography is remarkably incomplete, and even such a subject as vaginitis due to *Trichomonas vaginalis* is completely ignored. Witherspoon uses this text to propound his pet theories on stimulation by the estrogenic hormones as the cause of various gynecologic disorders, a fact that decreases the value of the book for the average student, who should get broader views.

Die Koronarinsuffizienz. Von Professor Dr. Franz Büchner, Direktor des Ludwig-Aschoff-Hauses, des Pathologischen Institutes der Universität Freiburg/Br. Kreislauf-Bücherei, Band III. Herausgegeben in Verbindung mit der Deutschen Gesellschaft für Kreislauforschung. Paper. Price, 6 marks. Pp. 88, with 49 illustrations. Dresden & Leipzig: Theodor Steinkopff, 1939.

In this short monograph the author develops the argument that coronary insufficiency constitutes an important form of heart disease. By coronary insufficiency is meant an inadequate blood supply to the heart relative to the work that it is doing. This coronary insufficiency may be acute or chronic and it may lead to heart failure. The electrocardiogram expresses coronary insufficiency through its abnormalities, particularly by deviations of the S-T segment. Anatomically the evidence of coronary insufficiency is found in microscopic focal regions of degeneration and necrosis disseminated through the area which was ischemic. Clinically the expression of the coronary insufficiency is anginal pain. Coronary insufficiency may arise (1) through mechanical interference with coronary blood flow, (2) through impairment in the quality of the coronary blood as far as its oxygen content is concerned or (3) through an increase in the work of the heart with which the coronary blood supply cannot keep pace. Cardiac hypertrophy, as the author points out, belongs to the last type. The monograph is well documented, and the arguments presented are quite convincing and in accord with the newer concept prevailing in this country. The only section which does not come up to the excellent standard is that dealing with the theory of the electrocardiographic changes in these conditions. This monograph is illumi-

nating of the trend of the times, since in it a pathologist admits that disease can occur because of functional disturbances and not necessarily because of an anatomic change. The author has helped to coordinate the structural disorders with this physiologic-clinical syndrome by demonstrating that coronary insufficiency has its anatomic signs. However, the pathologists must look carefully for this microscopic evidence. This monograph should be carefully read by those interested in the field, since it contains an excellent summary of Büchner's important contributions to the subject.

Clinique et pathologie comparée: Vénérologie, cancérologie, dermatose, médecine générale, phyto-pathologie. Par Louis Bory, chef de clinique de la Faculté de médecine de Paris à l'Hôpital Saint-Louis. Préface du Dr Flessinger. Paper. Price, 50 francs. Pp. 239. Paris: Masson & Cie, 1939.

The concepts of disease and medicine underlying this novel and interesting treatise are as broad as the concept of life itself. The only adequate scientific basis for medicine is that which views disease as an essential attribute of all organisms. Until the science of medicine recognizes this basic fact it proceeds without recognition of the evolution of diseases in the course of man's long ancestry. His diseases have evolved along with this ancestry and have left a part of their record in the organisms which have survived with man in the struggle for existence. Comparative pathology illumines the path of the evolution of human diseases. Even the reactions of plants to infection and functional disorders shed light on problems of immunity, resistance, recovery and death. The author approaches this subject through the field of dermatology, a logical approach because of the accessibility of the skin of man to the same or comparable infections as those which affect mammals. The book is divided into chapters on the venereal diseases of animals, syphiloid of the cat and human granulomatoses, tumors, cancers and leukoses, itch and demodiciasis, neoscrofula, paratuberculosis and paraprosoy, dermatoses, infectious icterus, the comparative pathology of epilepsy, the professional hazards of veterinarians and phytopathology. In a prophetic section on les maladies d'avenir, the author forecasts the increasing medical importance of brucellosis, psittacosis, icterohemorrhagic spirochetosis, infectious anemia of the horse, septic pyohemia, echinococcosis and diphtheria, all infectious and all associated with the biocenosis created by human society and the integrated animal life. The author advocates a fusion into one system of all instruction pertaining to animals and human beings in order that both may benefit from the comparative approach to clinical pathology. Even plant pathology has its contribution to make, notably in the field of the virus diseases. They too have their bacterial, fungous and nematode enemies and their necroses, tumors, immunities and processes of healing. This is a thought-provoking book. Its point of view is the logical social corrective for the opposition to medical research. It puts disease in its actual setting in relation to nature as a whole.

Medical Entomology with Special Reference to the Health and Well-Being of Man and Animals. By William B. Herms, Professor of Parasitology in the University of California, Berkeley. Based on the book known as "Medical and Veterinary Entomology." Third edition. Cloth. Price, \$5.50. Pp. 582, with 196 illustrations. New York: Macmillan Company, 1939.

The text is completely rewritten, based on the author's Medical and Veterinary Entomology (edition 2, 1923). In the interval of sixteen years much new material has become available in medical entomology. This is true especially in the fields related to public health, notably with reference to two of the greatest plagues of mankind, malaria and bubonic plague, both with insect vectors, the ubiquitous mosquito and the pestiferous flea, respectively. The book makes extensive use of the results of experiments and of the relation to public health of various insects. Nearly 100 pages deal with mosquitoes alone, discussing their classification, life history, food, flight, longevity, biting habits, mating and oviposition, and the special characteristics of the more banal species. Keys to the genera of culicids and to the species of anophelines of the United States are provided. A chapter is devoted to mosquitoes as vectors of disease. In addition to the three malarias they are the vectors of filariasis, several kinds of heartworm of dogs, yellow fever, dengue, bird malaria, equine encephalitis and fowlpox.

The author has had much experience in the organization and operation of mosquito abatement enterprises and his chapter on this subject is a mine of information, revealing the varied ramifications of the ecologic adaptations of the larval and imago stages of mosquitoes and their interplay with human factors ranging from public utilities to duck clubs. Cockroaches, bedbugs, cone nose bugs, lice, gnats, horseflies, houseflies, blood-sucking muscids, fleas, ticks and mites all come in for an exposure of their direct and vector relations to human and animal disease. The black widow spider is illustrated and discussed, and other venomous and urticarial arthropods from bees to centipedes are described. The medical uses of arthropods have an unexpectedly wide range. They include not only use of the long known Spanish fly, the use of honey on wounds and the curious utilization of the mandibles of decapitated ants and beetles in suturing wounds, but the more recent application of malarial infections in the therapy of dementia paralytica and arthritis, the surgical use of maggots, the use of bee venom and xenodiagnosis.

This book is not only a valuable textbook for entomologists and parasitologists but also an important reference work for the physician, public health officer, sanitary engineer and veterinarian. The illustrations are excellent, and significant bibliographies are included in each chapter.

Investigations sur le glaucome (essais). Par le Dr. E. P. Fortin. Paper. Pp. 47, with 34 illustrations. Buenos Aires: "El Ateneo," [n. d.]

For the past ten years Fortin has published in the Argentine and Spanish journals articles having to do with the maintenance of intra-ocular pressure. He has been interested in glaucoma especially from an anatomic point of view. The present pamphlet includes many beautiful illustrations of the iris angle and its environs, together with theories as to the production of glaucoma. Fortin believes that aqueous is evacuated from the anterior chamber by the action of the ciliary muscle sliding forward on the sclera. When the lens bulges forward in accommodation, additional space is needed and the aqueous is drained as the canal of Schlemm becomes more patulous. The action of the muscle of the ciliary body is compared to the heart action on the blood stream. Flaccidity of this muscle may cause glaucoma. The enlarged pupil of glaucoma is due likewise to a flaccid muscle, as the pupillary and the ciliary musculature have the same innervation. The pectinate "ligament" is misnamed, as there is no cordlike structure but simply a meshwork of tissue. Miotics act to close the ciliary muscle toward the axis of the eye, and thus the fluid is reduced in pressure. Particles of pigment cannot be a prodrome of glaucoma, as they would ordinarily be filtered out through the pectinate "ligament." Fortin believes that it is necessary to use physostigmine in the eye before these particles can be recognized. Iridectomy fails to relieve glaucoma, even though the canal of Schlemm is opened, if the pectinate "ligament" is not destroyed. At present the views of Fortin have not been generally accepted. The contribution in French leaves much to be desired because of language difficulties. Its value remains to be seen, although the ideas are of much interest to physiologists and ophthalmologists.

Surgical Treatment of Hand and Forearm Infections. By A. C. J. Brickel, A.B., M.D., Departments of Anatomy and Surgery, Western Reserve University, Cleveland. Cloth. Price, \$7.50. Pp. 300, with 201 illustrations, including 35 plates. St. Louis: C. V. Mosby Company, 1939.

This clinical, anatomic and experimental treatise on the surgical treatment of infections of the hand and forearm is well done and clear. T. Wingate Todd endorses the anatomic accuracy of the anatomic portions and illustrations. The colored plates are excellent. Some of the anatomic illustrations are done in black and white with the opposing page in color. The photographs of infected hands do not tell the story as well as the excellent drawings do. Roentgenograms of the hand after injection of radiopaque material are included. The book furnishes a quick reference for the busy practitioner. Every general, industrial and orthopedic surgeon should be acquainted with its contents. It is only by means of anatomic knowledge, clinical research and experience that scientific treatment can be developed. Treatment is successful only as it is based on facts.

Worth's Squint or the Binocular Reflexes and the Treatment of Strabismus. Seventh edition by F. Bernard Chavasse, M.A., D.M., Surgeon, Eye Department, Liverpool Eye and Ear Infirmary, Liverpool. Cloth. Price, \$8. Pp. 688, with 225 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1930.

The present edition of this classic on squint differs greatly from all previous editions. As Chavasse comments in the preface, "The possibility of rewriting the book (previous editions) was very carefully considered. It then became clear that it was not possible—or even desirable—to rewrite a classic." Since the fundamental researches of Helmholtz, Hering, Tschermak, Javal and Worth, a new conception of the phylogeny, the ontogeny and the physiology of the muscles of the eye has been created by Sherrington, Magnus and Pavlov. Hence the author has added a subsidiary title to the book, and he transmits this point of view in his detailed consideration of such factors in squint as the anatomy and physiology of the foundations of binocular reactions, the anatomic and reflex development in the child and the pathology of binocular anomalies. The last includes an insight into the obstacles of reflexes, their sight and nature, heterophoria and dissociation by primary sensory obstacles, and dissociation by primary motor obstacles. The difficulties encountered in accommodational and refractive states in the production of squint are thoroughly discussed. Both functional and somatic reactions to dissociation, inhibitions and the effects of secondary correspondences are well illuminated by case reports. Section IV is devoted to the diagnosis of the deviation, the state of sensory correspondences and the cause of the squint. The section on treatment includes treatment of the cause, of the secondary sensory correspondences and of the deviation and, finally, the technic of certain operations. An appendix of illustrative cases completes the volume. These are selected to show the salient features of the various types of strabismus and include many cases observed during the past fifteen years at the Eye and Ear Infirmary of Liverpool, which was established in 1820. This edition encompasses far more than does anything else which has been written concerning squint. The illustrations are simple and clear. The print is large and well spaced. While authorities are mentioned by name, there is no bibliography. An index of seven pages is ample. Chavasse has indeed rewritten in a manner most commendable a classic that has withstood the test of thirty-five years. Its usefulness to those interested in the study of binocular vision and parallelism of the eyes is obvious.

Fundamental Principles of Bacteriology with Laboratory Exercises. By A. J. Sallie, B.S., M.S., Ph.D., Assistant Professor of Bacteriology, University of California, Berkeley. Cloth. Price, \$4. Pp. 679, with 215 illustrations. New York & London: McGraw-Hill Book Company, Inc., 1939.

This is an interesting attempt to teach general bacteriology to elementary students by a new approach. Most textbooks are written from a taxonomic point of view and consequently tend to overemphasize classification and morphologic and biochemical characteristics of bacteria. The author has successfully avoided this and has chosen a harder but more logical method to present principles that are not only of more interest to the general student but might even be expected to be retained by him for a reasonable time. It is not to be expected that critics will agree entirely with the material selected by the author. To appreciate many of the discussions, something more than elementary courses in inorganic and organic chemistry are required. The book is replete with complicated chemical formulas showing the end products of enzymic action, the structure of dyestuffs and the decomposition products of proteins, organic phosphorus compounds and others. While the reader is indebted to the author for gathering in one volume these complex formulas and the reactions which they represent, they would seem to belong in an advanced rather than in an elementary textbook. It is not necessary to describe in detail the subjects treated. They cover the entire range of bacterial activity and are presented in a readable and accurate manner, although with more detail in some instances than seems desirable. Laboratory exercises are included and these are rather better than usual. They are designed to teach principles rather than technic. It is refreshing to read a textbook which is an honest attempt to present material that most teachers know should be given to the elementary student but which is more difficult for the teacher than the more orthodox courses offered in our colleges.

A Text-Book of Pharmacognosy. By George Edward Trease, B.Pharm., Ph.C., A.I.C., Lecturer on Pharmacognosy in the University College of Nottingham, Nottingham. With Contributions by R. Blenfang, B.S., M.S., Ph.D., et al. Third edition. Cloth. Price, \$6. Pp. 739, with 243 illustrations. Baltimore: William Wood & Company, 1939.

This work has won recognition in all English speaking countries. The present edition has been thoroughly revised and enlarged. Some rearrangement of the order of presentation has been made, this order now being: part I, general principles, including historical introduction; part II, microscopy, including discussion of apparatus and reagents and a review of histologic features of pharmacognostic importance; part III, drugs of vegetable origin, with morphologic and botanic classifications; part IV, drugs of animal origin, and part V, physical and chemical methods of drug analyses. Included are ten maps showing the geographic source of drugs and a glossary of Latin words used in naming species. Pharmacognosy at present is definitely a subject for students of pharmacy and includes much that is of little interest to physicians. Medical students get little or no instruction in it. However, physicians who are interested will find this a satisfactory work and also interesting. Clarity of presentation is an important feature.

Royal Northern Operative Surgery. By the Surgical Staff of the Royal Northern Hospital. Cloth. Price, £2.2s. Pp. 551, with 463 illustrations. London: H. K. Lewis & Co., Ltd., 1939.

Printed on fine paper and containing excellent illustrations, this is a beautiful exposition of the surgical technic carried out by the members of the staff of an English hospital. The material is in a strictly anatomic arrangement and covers the entire body and its structures. The treatment of fractures is not included except that of the femoral neck. As a rule only one operation is cited for any given problem, and this represents the usually accepted technic for that hospital. As can be expected there is not much that is new or different in this book, although the methods described are usually modern. The authors have adopted the electrocoagulation method of cholecystectomy advocated by Thorek. The size and purpose of this volume obviate any attempt at comprehensiveness. Nevertheless it is a pleasant and refreshing book to peruse.

A Fundamental Approach to Bacteriology. By Courtland Sawin Mudge, Ph.D., Associate Professor of Dairy Industry, University of California, San Francisco, and Floyd Russell Smith, Ph.D., Instructor in Dairy Industry, University of California. Paper. Price, \$3. Pp. 265, with 17 illustrations. San Francisco: J. W. Stacey, Inc., 1939.

This is an approach to bacteriology primarily through the laboratory. The book is built around laboratory exercises and demonstrations with explanations and description intended to prepare the student for an understanding of the work he is about to perform. The laboratory work covers that usually presented in courses in general bacteriology, and the selection of exercises is excellent. The descriptive matter is presented in a conversational style not infrequently found in secondary school laboratory textbooks in the sciences. Although accurate and sufficient for the purpose of an elementary course in bacteriology, it is doubtful that this method will appeal to most college students. The authors make no claim that the book is more than a laboratory manual written in a somewhat unconventional manner and admit that it does not have the "dignity of the usual text." Both of these statements are true.

Hair-Dyes and Hair-Dyeing Chemistry and Technique. By H. Stanley Redgrove, B.Sc., F.I.C., F.R.H.S., and the late Gilbert A. Foan. A new edition completely revised by H. Stanley Redgrove and J. Barl-Woolfs. Cloth. Price, \$5. Pp. 205, with 33 illustrations. New York: Chemical Publishing Company, Inc., 1939.

This small book is invaluable to the hair dresser and brings much of value and interest to the layman and physician. The reader is first impressed by the great complexity of the subject. The number of dyestuffs, good and bad, harmful and less harmful, their innumerable combinations and the careful technic that must be followed in their successful use explain clearly why the practicing physician, who is only an amateur at best in his knowledge of hair dyeing, cannot give adequate advice on how to do it. He can only tell the prospective dyer to consult the best available hair dresser and to insist on a preliminary patch test, for "para," the hair dressers' name for paraphenylenediamine, is almost sure to be an ingredient of every effective hair dye.

On page 144 directions are given for the patch test, called the Sabouraud-Rousseau test. The use of eau de cologne as

one of the cleansing agents preliminary to the patch test can be criticized as introducing other allergens, which may confuse the interpretation of the result. Criticism can also be made of this statement, on page 111: "It is interesting and important to note that in the case of a person idiosyncratic towards an 'eczematogenous substance' the abnormal skin reaction seems to be independent of the concentration of the substance, in which respect the reaction is totally different from that of poisoning." The fact is that concentration has a great deal to do with allergic reactions. Considering the professions of the authors, however, one must agree that there are remarkably few opportunities for criticism even when they discuss subjects as difficult as allergy.

Treating of the danger of dermatitis from hair dyes, the authors are frank in acknowledging the facts and in warning of the danger. Particularly in respect to the exceedingly dangerous practice of using dyes containing "para" for the coloring of eyebrows and lashes do they give emphatic warning. While strongly advising against the attempt, they give minute directions for minimizing the danger if it is undertaken. British hair dressers are still playing with this fire.

The book is well written, thorough and easy to understand. It treats of the structure of the hair, bleaches, dyes of various kinds and degrees of excellence, "brightening shampoos" and "rinses" and the technics of the various procedures and ends with a chapter on the causes of gray hair, with some hints to those who wish to avoid premature grayness.

Infections of the Hand: A Guide to the Surgical Treatment of Acute and Chronic Suppurative Processes in the Fingers, Hand and Forearm. By Allen B. Kanavel, M.D., Sc.D. Seventh edition. Cloth. Price, \$6. Pp. 503, with 229 illustrations. Philadelphia: Lea & Febiger, 1939.

Dr. Kanavel, whose tragic death on May 27, 1938, was a great shock to the medical world, has left for posterity and humanity a monumental work on infections of the hand, revised and brought down to date a short time before his death. There are four parts to the volume. The first is concerned with the anatomy of the hand with reference to infection, the second with localized infections and clinical entities, the third with lymphangitis, fascial space and tendon sheath infections, and the fourth with complications, sequelae and after-treatment of infections of the hand. Special emphasis is placed on the prevention of deformities and on treatment with function always in mind. The treatment of sequelae of infections has been stressed more in this than in preceding editions. The volume is generously supplied with reproductions of roentgenograms and photographs, diagrams and anatomic illustrations.

A Textbook of Surgery. By American Authors. Edited by Frederick Christopher, B.S., M.D., F.A.C.S., Associate Professor of Surgery at Northwestern University Medical School, Chicago. Second edition. Cloth. Price, \$10. Pp. 1,695, with 1,381 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

An imposing array of surgeons has been mustered to compile a textbook of surgery of exceptional value and authority. The constant state of flux permeating the field of surgical knowledge has created in its wake a host of specialists in a field already highly technical. These specialists have combined their efforts to produce in almost seventeen hundred full pages a standard textbook on surgery to be written. The material content expresses the opinion of each author and, while differences exist, it is impossible for a reviewer to draw conclusions on the individual contributions. He must either concur or differ with the mode of presentation, a duty which is rightfully relinquished to the discriminating reader. The comprehensive scope of this single volume makes it a genuine epitome of modern surgery. General surgery and the specialties alike are subdivided and receive exposition from a varying number of physicians. The brief bibliographic lists following many of the chapters contain recent references and further enhance the study of any topic. There are numerous illustrations of variable value. The reproduction of the roentgenograms in general is not wholly satisfactory. The great advantage in a book of this sort is the thoroughness with which it can undergo revision. A new edition, therefore, will usually contain much new material and little floating dead wood. While too advanced for the average student, this book will serve well the postgraduate student of surgery and the practicing physician, surgeon or internist.

Clinical Biochemistry. By Abraham Cantarow, M.D., Associate Professor of Medicine, Jefferson Medical College, Philadelphia, and Max Trumper, Ph.D., Clinical Chemist and Toxicologist. With a foreword by Hobart A. Refaiani, M.D., Professor of Medicine, Jefferson Medical College. Second edition. Cloth. Price, \$6. Pp. 666, with 15 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

The task of adequately discussing the many biochemical subjects which find important applications in clinical medicine and surgery in a comparatively short textbook is admittedly difficult. Under the new title "Clinical Biochemistry" the authors have extensively revised and supplemented the material presented in the first edition. Chapters or sections are devoted to the metabolism of carbohydrates, proteins, lipids, chloride, calcium, inorganic phosphorus, magnesium, iron, iodine, sodium and potassium and to the topics of phosphatase activity, acid-base balance, respiratory exchange and basal metabolism, vitamins, renal function, hepatic, gastric and pancreatic function, cerebrospinal fluid and water balance. The normal picture is presented and the abnormal conditions bringing about disturbances are emphasized. Attention is given principally to changes of the blood constituents in the various disease conditions. The summary chapter on the most important chemical changes which may be utilized in diagnosis and prognosis of various diseases or conditions should be helpful. Although criticism might be found for inadequacy of material and citation of the literature in certain sections, the text, on the whole, should prove of considerable value to the practicing physician who wants a review of the various topics to be better able to select biochemical determinations to aid in diagnosis and prognosis. More attention, however, could have been given with advantage to the choice of biochemical methods to be employed.

Petite chirurgie et technique médicale courante. Par G. Roux, professeur agrégé à la Faculté de médecine de Montpellier. Cloth. Price, 120 francs. Pp. 591, with 361 illustrations. Paris: Masson & Cie, 1938.

The objective of this book is the presentation of the principles of minor surgery and medical technic to advanced students, interns and young assistants. The author set out to embrace not only such subjects as preoperative and postoperative care, emergency treatment of fractures, blood transfusions, minor surgical procedures and the customary methods of clinical investigation, e. g. determinations of the blood pressure, gastric lavage and parenteral administration of drugs, but also heliotherapy, hydrotherapy and minor otorhinolaryngologic, ophthalmologic, urologic and gynecologic interventions. The material is divided into short sections and paragraphs, each with subheadings that indicate its contents. A fastidious, lengthy description of such vast material was purposely omitted in an attempt to present a concise but comprehensive guide to bedside diagnosis and treatment. Many methods, instruments and apparatus described in the book and named after French authors are known to the American student under different names, and in view of the variance in the terminology this manual would be of little value to him. The author seems to have taken too big a bite and as a result many subjects are treated in an inadequate manner. To be brief but complete, a synopsis must necessarily limit itself to a relatively narrow field. An attempt to familiarize the young assistant with the popular methods of diagnosis and with therapeutic technic in all branches of medicine must result in a superficial, incomplete and therefore less valuable presentation.

The Patient is the Unit of Practice. By Dnane Willard Propst, A.B., B.S., M.D., Assistant Professor of Medicine, University of Illinois College of Medicine, Chicago. Cloth. Price, \$3.50. Pp. 219, with 9 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1939.

The author of this book tries to systematize medicine so that it can be utilized by the student in a chartlike fashion. He discusses at length the constitutional potentialities of disease and the psychogenic factors concerned in the patient's attitude toward his problem. A great deal of space is taken up by the psychosomatic approach. In his "diagnostic or working hypothesis" he reports a case of numerous functional complaints associated with delusions and illusions. However, even after meticulous observations no examination of the spinal fluid is reported and no diagnosis is made as to the mental aspect of the patient. He goes at length into the various diagnostic procedures, which, of course, are exceedingly elementary. The

charts are not at all inclusive. For instance, the chart on the etiology of dyspnea is so confusing that it emphasizes the necessity for the student to have a photographic mind. The therapeutic principles outlined are divided into rest, diet, symptomatic treatment and psychotherapy. He emphasizes at great length the relation of weather conditions to disease. He is particularly interested in the biosocial classification of mankind. All in all the book is a philosophic approach to the problems of medicine from the point of view of both diagnosis and treatment. This probably represents a hobby of the author and should not be taken too seriously as the best method of teaching medical students the importance of medical facts; nor does it arouse the curiosity of the student toward an investigative approach.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospitals: Liability of Charitable Hospital for Injury to Pay Patients.—A hospital conducted in the interest of charity, the Supreme Court of Idaho held in *Wilcox v. Idaho Falls Latter Day Saints Hospital*, is not liable to pay patients injured through the negligence of hospital employees, even though the hospital may not have exercised due care in the selection of the negligent employee. The court based its holding on the ground that one who accepts the benefit of a charity enters into a relation which exempts the benefactor from liability for the negligence of his servants in administering the charity. The articles of incorporation of a hospital, the court said, are admissible in evidence to establish a disputable presumption as to the charitable status of the hospital. In this case a child was taken to the hospital for treatment for pneumonia. Her attending physician directed that she be given diathermy treatment. The treatments were administered by a hospital nurse during the course of which the child sustained a severe burn.

In *Sisters of the Sorrowful Mother v. Zeidler*, the Supreme Court of Oklahoma held that a pay patient in a charitable hospital may recover damages for injuries sustained through the negligence of a servant, agent or employee of the hospital. The doctrine of nonliability, the court said, was "repugnant and shocking to a sense of fairness and justice to the victim of what may aptly be termed protected negligence." In this case, a woman was taken to the hospital in a delirious condition. Due, it was alleged, to the negligence of hospital employees in leaving her unattended, she fell or jumped from a second story window, death resulting.—*Wilcox v. Idaho Falls Latter Day Saints Hospital (Idaho)*, 82 P. (2d) 849; *Sisters of the Sorrowful Mother v. Zeidler (Okla.)*, 82 P. (2d) 996.

Health Insurance: Impacted Wisdom Teeth Not a Disease.—The defendant insurance company issued, Sept. 4, 1936, a policy insuring the plaintiff against "loss from disease contracted during the life of this policy and after it has been maintained in continuous force for thirty (30) days from its date." Within thirty days thereafter the plaintiff's dentist informed her that she had four impacted wisdom teeth. She had suffered no pain or illness from them and was not aware of the condition. On October 5 the impacted teeth were extracted and the plaintiff was unable to do any work for the succeeding five weeks. She brought suit on the policy. The trial court overruled motions of the insurance company for a judgment of nonsuit and entered a judgment in favor of the plaintiff, and the insurance company appealed to the Supreme Court of North Carolina.

The sole question before the court was whether or not the disability of the plaintiff resulted from a disease. The term "disease," said the court, has been defined as "an alteration in the state of the human body . . . or of some of its organs or parts interrupting or disturbing the performance of the vital functions, or of a particular instance or case of this"; as "deviation from the healthy or normal condition of any of

the functions or tissues of the body," and as "a morbid condition of the body." Black's Law Dictionary, ed. 3, 18 C. J. 1139. Obviously, then, the impacted teeth did not constitute a disease. The plaintiff did not know of the condition until so informed by her dentist; the teeth had given no trouble or pain; there was no disturbance in the performance of any of the functions or tissues of the body and no morbid condition existed. The sickness and disability following the extraction of the teeth were the results of the extractions to which the plaintiff voluntarily submitted; she might never have had any trouble, pain or sickness from the teeth if they had not been removed. Even if it is conceded that the impacted teeth constituted a disease, the evidence was clear, the court said, that the condition had existed for a long time prior to the lapse of thirty days following the issuance of the policy.

The trial court should have sustained the motion of the insurance company for a judgment of nonsuit. The judgment for the plaintiff was therefore reversed.—*McGregor v. General Acc. Fire & Life Assur. Corporation (N. C.)*, 198 S. E. 641.

Workmen's Compensation Acts: Cancer of Tongue Due to Inhalation of Sulfuric Acid Spray an Occupational Disease.—Boal, the plaintiff, had been employed for more than ten years as a "pickler" in one of the pickling rooms in the defendant company's storage battery plant. In the process of pickling used by the defendant, lead plates or "grids" for storage batteries were arranged on wooden racks inside of large tanks into which was piped a solution of sulfuric acid and water. After the tank was drained, the picklers removed the lead plates while still damp and placed them on trucks. The wooden racks were also removed and piled in the same room. Both the plates and the racks were allowed to dry in the pickling rooms. As a result of this operation, Boal and the other picklers were constantly exposed to and had to inhale a mist, a spray or the fumes of sulfuric acid, which commonly caused coughing, dryness of the mouth and smarting of the skin. A cancer developed on the right side of Boal's tongue. He brought suit at common law in the United States district court, E. D., Pennsylvania, against his employer, claiming that his cancer had been caused by the inhalation of the mist, spray or fumes of sulfuric acid. He alleged that the defendant company had negligently failed to warn him of the danger incident to his employment and to provide ventilating facilities or other devices for his safety. From a judgment of nonsuit, Boal appealed to the United States circuit court of appeals, third circuit.

Uncontradicted testimony showed that Boal's cancerous condition was so serious that death would result in a relatively short time. Expert witnesses testified that the inhalation of or exposure to the spray of sulfuric acid was the proximate cause of Boal's cancer. A pathologist testified that exposure to a mist of sulfuric acid would cause dehydration and disturbance of function of the cells of the mouth. A specialist in industrial toxicology, a chemist, testified that exposure of the cells of the mouth to a spray of sulfuric acid would cause physical damage to them and that the continued irritation or chemical trauma would eventually give rise to ulceration. Two physicians testified that such prolonged chemical irritation of the mucous membranes of Boal's mouth caused an ulcer to develop and in turn caused the unhealed ulcer to develop into cancer.

The defendant contended that its failure to provide ventilating facilities did not constitute actionable negligence, because the precautionary measures taken by it for the safety of its employees came up to the general standards prevailing in the industry. With this contention the circuit court of appeals was not in accord. The specialist in industrial toxicology testified that the defendant's practice of allowing the lead plates and the wooden racks to dry in the pickling rooms was "really the vice or error in the case, or in this working condition," and that in no pickling process in any industry was such procedure considered to be good practice. In fact, as he testified, a common procedure in the pickling of metal is to transfer the metal directly from the pickling vat to a conveyor which carries the metal away automatically, an exhaust or warm air system being used to prevent any mist of sulfuric acid getting into the air.

Neither could the court agree with the defendant's contention that it was not negligent in failing to warn the plaintiff of danger

because such danger was not known to it. The evidence showed that the defendant could have known of the danger if it had exercised due and proper diligence. General scientific knowledge existed on this subject which the defendant could have ascertained from various publications and from persons acquainted with the art, if proper inquiry had been made. One of the medical witnesses testified that "sulfuric acid is notorious for causing a type of ulcer which is indurating and doesn't tend to heal," and that "even in very low concentrations there would be definite damage done to the person breathing these fumes." Nor could the court agree with the defendant's further claim that it did not and could not know that cancer would develop from exposure to sulfuric acid fumes. The fact, as the defendant pointed out, that there was no record of and none of the expert witnesses could recall any other case in which the inhalation of fumes of sulfuric acid resulted in cancer was not conclusive, for the effect of such fumes on different persons would vary according to individual physical resistance. Where an employer knows or is presumed to know that a danger exists, it is not necessary that he should have contemplated the particular consequences, the form of the accident or the nature of the injury, and the fact that an accident is unusual, extraordinary or even unheard of does not relieve the employer of liability.

In the judgment of the court, the plaintiff was not precluded by the Pennsylvania workmen's compensation act from maintaining this common law action in tort. Under that act, diseases caused or aggravated by accident are compensable, but diseases of gradual development, or occupational diseases, are not compensable. The court disagreed with the defendant's claim that because cancer is not a disease known by common experience to result from the occupation of pickling metal, Boal was not suffering from an occupational disease. Occupational diseases are not limited to those diseases which are known by common experience to have resulted from a certain occupation.

Accordingly, the circuit court of appeals reversed the judgment of nonsuit and ordered a new trial.—*Boal v. Electric Storage Battery Co.*, 98 F. (2d) 815.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Prognosis in Diabetic Coma: Basic Importance of Mental State. L. B. Owens and S. S. Rockwern, Cincinnati.—p. 252.

Colloidal Aluminum Hydroxide for Peptic Ulcer.—Woldman and Polan have now employed the continuous administration of colloidal aluminum hydroxide for three years in the treatment of 407 patients with peptic ulcers. The treatment represents no radical departure from the methods that have been in use for many years, all of which have been designed to counteract the effects of excessive acid secretion in the stomach. The drip treatment with colloidal aluminum hydroxide merely emphasizes and expands this principle by the use of a more effective neutralizing agent administered continuously instead of intermittently. The corrosive action of hydrochloric acid is the most formidable antagonist to the healing process. If the factors causing the ulcer are dominant over the natural healing process, the lesion progresses steadily. On the other hand, if the factors producing the ulcer are satisfactorily controlled, then the balance shifts in favor of healing. It follows that treatment, to be satisfactory, should protect the ulcer from acid corrosion continuously. Otherwise the accumulation of acid at night may destroy some of the granulation tissue formed during the day and thus delay or prevent healing. In addition to its exceptional neutralizing effect, colloidal aluminum hydroxide appears to promote healing by coating the lesion with a jelly-like, protective mass, and by its astringent effect. The most striking features of this treatment are prompt relief of pain, rapid healing of the ulcer, healing of refractory ulcers unsuccessfully treated by other methods and excellent results in bleeding ulcer.

Of 101 patients with massive hemorrhage treated, only three died. The authors do not claim that this regimen can prevent the recurrence of ulcers after they have been healed. Nevertheless, thirty patients who have continued to take colloidal aluminum hydroxide by mouth for two years or more have been followed closely throughout the entire period, and none of them have had a recurrence, although previously a number of them had had exacerbations of ulcer symptoms two or three times annually for several years. Laboratory studies made on these patients showed that the drug had no harmful effect.

Influence of Overweight on Blood Pressures.—In evaluating the effect of overweight on blood pressure, Short and Johnson determined the systolic and diastolic pressures of 2,858 overweight and, for comparison, 658 normal weight men, all in supposedly good health. The authors also consider the effect of both the degree and the duration of obesity on hypertension and state that it is unfortunate that these contributory factors have usually been ignored in previous studies on the subject. All the men were ambulatory, about their usual occupations. They applied for the periodic health examination provided by insurance companies carrying their several policies. They have been unselected for the study except for the factor of overweight. Those having a systolic pressure of 150 mm. or higher were considered as having systolic hypertension and those having a diastolic pressure of 90 mm. or higher as having diastolic hypertension. The subjects were divided into weight groups as follows: a "normal" weight group whose weights ranged from 5 per cent under to 5 per cent over "ideal" weight, and overweight groups of from 6 to 15, 16 to 25, 26 to 40 and 41 or more per cent above "ideal" weight. For systolic blood pressure there was virtually no increased incidence among those of normal weight. There was, however, a moderately increased incidence for each overweight group up to 40 per cent, at which point the incidence of hypertension was 10 per cent, while in the group more than 40 per cent overweight there was a sharply increased incidence of hypertension to more than 30 per cent. The incidence of diastolic hypertension exceeded that of systolic hypertension in all ranges of overweight and, in general, showed a progressive increase to more than 35 per cent in the highest weight group. The difference in average blood pressures was greatest in the age group from 50 to 59 years. The incidence of hypertension in the overweight group was generally lower than reported by other observers. Average blood pressures were consistently higher in the overweight group, but not so great as had been expected. The authors are inclined to agree with Mosenthal that the influence of overweight on blood pressure has probably been somewhat exaggerated.

Dark Adaptation Under Reduced Oxygen Tensions.—McFarland and Evans measured the phenomena of the darkening of the visual field under anoxia by the usual procedures used in studying night blindness. Each of the twenty subjects (students and physicians) went through a practice period of two hours, during which time the dark adaptation test was given repeatedly. This was sufficient so that each subject's report was consistent. The dark adaptation curves (plotting threshold against time) were progressively elevated with

increasing oxygen deprivation. These effects were counteracted within two to three minutes by inhaling oxygen. The diminution in light sensitivity was statistically significant for all but five of the eighteen subjects at the first simulated altitude of 7,400 feet, for all but one at 11,000 feet and for the entire group at 15,000 feet. The magnitude of these changes was 0.1, 0.22 and 0.4 of a log unit, respectively. These effects are probably of no great practical significance in relation to night blindness in a pilot until altitudes of approximately from 10,000 to 12,000 feet are attained. In the authors' opinion the results obtained in this experiment suggest that the changes are not concerned with the photochemical substances of the retina but with the neural elements of both the retina and the central nervous system.

Giant Bullae and Anthracosilicosis.—A case of multiple giant bullae of the lung associated with anthracosilicosis, proved clinically and roentgenologically and substantiated by gross post-mortem observations and microscopic examination, is reported by Wiese and his associates. They believe this case to be unique because of the multiplicity and the size of the bullae, which could readily have been mistaken for spontaneous pneumothorax.

Roentgen Therapy for Otitis Media.—Brown and his co-workers state that the roentgen treatment of acute and chronic otitis media is rational because of all the body cells the lymphocytes are the most sensitive to the rays. Lymphocytic infiltration is a major and constant feature of inflammation and infection of the middle ear, and breaking down these cells relieves pressure within the cavity and thereby relieves pain. Roentgen irradiation also promotes phagocytosis, which progresses rapidly until the lymphocytes are almost entirely destroyed. The polymorphonuclears and eosinophils undergo disintegration somewhat less rapidly. In addition to this cellular destruction and phagocytosis, the x-rays are believed to liberate enzymes, antibodies and other unknown principles which also aid in the processes of autolysis and liquefaction. The technic that the authors employed has varied. At present they are using 85 kilovolts (peak), 5 milliamperes, 16 inch target-skin distance and 1 mm. of aluminum filter. They do not follow a hard and fast rule as far as dosage is concerned but take into consideration the severity or duration of the condition and the age of the patient. In mild cases in infants they have used from 50 to 60 roentgens and in young children and adults the dosage has varied from 60 to 100 roentgens. Their cases of acute catarrhal otitis media required only one treatment. In cases of acute purulent otitis from three to seven days elapsed between treatments, depending on the condition of the ear. Patients with chronic purulent otitis received treatments about ten days apart. In acute otitis media if the temperature was not more than 99.6 F., with bulging of the drum and obliteration of the short process, irradiation was not preceded by myringotomy. Only one of thirty-one cases of acute catarrhal otitis media required myringotomy following therapy and in this instance myringotomy had been refused by the parents and roentgen therapy was tried as the only resort. The majority of the cases were seen within the first twenty-four or forty-eight hours. The average number of roentgens was 72.9 and the number of days required for the drum to return to normal was 3.15. Of eighteen cases of acute purulent otitis media, myringotomy was performed in twelve, while spontaneous rupture of the drum

membrane occurred in the other six within twenty-four hours of being seen. The duration of symptoms before the first examination varied from three days to six hours. These patients received an average of 1.33 treatments, with an average of 70 roentgens. The ears were dry and the drums were normal within an average of 8.16 days. Four patients required two treatments and one patient three treatments. None of the eight cases of chronic purulent otitis media, with a history of an intermittent discharging ear of from four months to eight years, required myringotomy, the opening in the drum being of sufficient size to afford excellent drainage. Six patients received only one treatment, one received two treatments and one received three treatments. An average of 64.54 roentgens was given. The ears were dry within an average of 11.63 days. In nine of eleven cases not classified an initial roentgen treatment was given and the patient did not return for further observation, one was finally cured and one was afforded considerable relief. In conclusion the authors state that instead of mastoidectomy it now seems that not only will a short series of roentgen treatments suffice to cause an ear to become dry and free from pain, but hearing will be fairly normal in it. None of their cases have shown any complication following this mode of therapy.

Recovery of Nerve Function in Skin Transplants.—Kredel and Phemister followed up for periods up to nine years eleven patients with skin transplants, chiefly pedicle flaps, for evidence of sympathetic recovery. Sudomotor, vasomotor, pilomotor and sebomotor functions were studied and correlated with the recovery of sensation. The study shows that a considerable amount of sympathetic nerve function may return to transplanted pedicle skin flaps. Variability in the rate and extent of recovery is marked. Adequate return of associated sensation, particularly of light touch, seems a necessary factor in sympathetic recovery. In case 1, in which there was considerable delay in return of light touch distally, sweating was not recovered in the lower portion of the skin transplant on the lower part of the right leg. In case 8, in which there was no recovery of touch, there was no sweating twenty-two months after the transplantation of a skin flap from the abdomen to the left forearm. In case 7 delayed and incomplete recovery of touch and of sympathetic functions was shown in the lower portion of the skin flap on the heel. In the tubed pedicle transplanted from the back to the undersurface of the chin in case 4 sweating was recovered only over the basal area of recovery of touch. The presence of deep scarring about a flap limits sympathetic as well as somatic nerve regeneration to all or to parts of a flap. Return of sudomotor and sebomotor function may be of some practical importance in keeping a flap clean. Three patients had some annoyance in this regard. However, infection was not observed to result from accumulation of dirt. Inadequate vasomotor function results in variations in color of the skin, which are undesirable from a cosmetic standpoint. Some of these vasomotor disturbances may persist if abnormal regeneration of sympathetic nerves to blood vessels has occurred. Some flaps remain hypersensitive to cold. The failure of thin free grafts to recover skin secretions is explained by the fact that many of the sweat and sebaceous glands are left behind, as well as by inadequate nerve regeneration due to fibrosis of the bed. Apparently, the small amount of duct epithelium

included in thin grafts prevents regeneration of functional secreting glands in Thiersch grafts. To what extent sweating may be recovered in the thicker types of free grafts deserves further study. Some return of sweating has been observed several years after lumbar and cervicothoracic sympathectomy for Raynaud's disease.

Cholesterol in Epilepsy.—Aird and Gurchot studied the effect of intravenous and parenteral injections of cholesterol on the convulsive threshold of white mice in which experimental epilepsy was induced by convulsive doses of cocaine hydrochloride. In conclusion they state that direct parenteral injection of cholesterol resulted in a marked rise in the threshold for convulsive doses of the cocaine. Both a colloidal suspension of cholesterol in water and a solution of cholesterol in olive oil showed this protective effect. After a series of protective injections of cholesterol, the convulsive effects of cocaine hydrochloride were more delayed in onset than the corresponding effects in control groups. This was interpreted as indicating delayed absorption of the convulsive agent. The protective effect likewise was explained on this basis. The results of the study were interpreted as consistent with the theory that the vital lipids play a significant part in the permeability of cell membranes and through this mechanism are an important factor in epilepsy.

Partial Thoracoplasty Without Deformation.—Iselin and Arp state that the deformity resulting from a routine thoracoplasty is due to three causes: (1) vertical lowering of the scapula with subsequent fall of the shoulder, (2) sinking of the scapula into the depth and its lateral projection and (3) scoliosis, with convexity toward the side on which operation was done. It is their opinion that from the orthopedic point of view the removal of the transverse processes of the vertebrae is a mistake and conclude that, to cause no deformity, thoracoplasty should not involve the trapezius muscle, the angular and rhomboid muscles or the latissimus dorsi muscle, since these muscles fix the scapula. By modifying the direction of Picot's incision and cutting some of the trapezius fibers (the ascending fibers which play no part in fixation of the shoulder) they were able to perform thoracoplasties involving as many as six ribs and to perform extrafascial apicolysis under conditions far more favorable than those obtained in making the usual incisions around the scapula. The cutaneous incision is oblique, starting at the seventh cervical vertebra (the prominent one) and extending as far as 3 cm. below the angle of the scapula. The upper part of the incision does not have to reach the seventh cervical vertebra but starts at 1 cm. from it; if necessary, its lower extremity may be prolonged along the spinal border of the scapula. This incision allows a favorable approach to the most difficult point in surgical treatment of pulmonary tuberculosis: ablation of the first rib, the key of the thoracoplasty. With this incision the ribs can be viewed one after the other. Extrafascial apicolysis is much more easily performed with this incision, as the apex of the lung is exactly in the center of the wound. A set of instruments suitable for the operation is necessary. The authors describe their use. They consist of

two Semb retractors, two strong double-bent retractors, three rugines, Brünner's costostome for costostomy and two spatulas of the type employed by Semb. The scapula can be easily retracted in spite of the preservation of its muscles. This is done by putting the patient flat on his stomach and raising the arm, which places the bone in the sagittal plane and entirely disclosed from the thorax. It is maintained in this position by means of a retractor. Some of the advantages of this incision, the authors point out, are that it provokes little hemorrhage and, as the muscle is not cut, it does not cause shock. Reconstruction is simple: the ascending fibers of the trapezius muscle which have been cut must be carefully sutured. The dissociated muscular parts are brought together by means of two sutures, as in McBurney's incision. The results are excellent. For the last two years the authors have used this incision for all thoracoplasties and extrafascial apicolyses.

Appendicitis.—The thesis that appendicitis in the majority of cases is a form of closed loop obstruction is developed in this paper. Bowers shows that in 80 per cent of 485 cases in his series the condition was on an obstructive basis and that in 67 per cent an impacted fecalith was the obstructing mechanism. He demonstrates that there is a direct correlation between the presence of a fecalith and subsequent development of obstruction with closed loop formation, eventuating in perforation and peritonitis if the obstruction is not overcome by expulsion of the fecalith or release of the obstruction by other means.

Morbidity from Operative Complications.—Of the 450 patients that Beck observed for operative complications (wound infections and pulmonary lesions) 332, or 73.8 per cent, had an uneventful convalescence, whereas 118, or 26.2 per cent, had some complication during the postoperative course; only "clean" operations were selected for the study. In no case was more than one complication reported. This may be due to lack of observation on the part of the person filling out the report but is more probably due to the fact that the presenting complication overshadowed the secondary one. There were five deaths in the series. Surgical shock and "gas pains" are not being considered. In the series there were fifty-six wound complications, most of which resulted from hematomas in the wound. When the edges of the wound are slightly raised and reddened, a hypodermic needle inserted into the wound will usually aspirate a small or moderate amount of old blood or of blood-stained purulent material; these are small hematomas rather than infections. Most of the twenty-eight pulmonary ailments in the group were classified as bronchitis. Whether or not this minor bronchitis represented small areas of atelectasis is not in the province of this discussion. There were eight lesions definitely classified as atelectatic. There were thirteen patients with complications referable to the urinary tract. There was usually mild cystitis, although there was one instance of violent cystopyelitis which resisted therapy. Only six of the patients had had retention of urine requiring catheterization. The complication arose most frequently in young persons. Thrombophlebitis of the femoral vein occurred in only two persons in the entire series. The other complications were so inconstant that discussion of them is not indicated. Many factors enter into the pathogenesis of the complications. To evaluate any one of them, all of the others must be kept at an absolute or relative value. However, in reviewing the practical lessons learned from the study, the author finds that probably the most important is that an explanation can usually be found for a temperature which remains over 99.6 F. for more than four days. If one is alert for this sign, one will be able to "pick up" far more of the complications which beset the surgical patient. If the complications are faithfully recorded, a cause and a cure for some of them will undoubtedly be found.

Current Conceptions in Epilepsy.—Brown states that it has been clearly demonstrated that epilepsy and other nervous and mental diseases occur more frequently among the ancestors and collateral relatives of deteriorated persons with epilepsy than among the general population. The offspring of persons with epilepsy are susceptible to it and defective mental development or other neuropsychiatric disorders. In a study of the hereditary factors in epilepsy, in which the records of non-deteriorated epileptic patients were used, it was found that the hereditary backgrounds of these patients are tainted with neuropathic disturbances to a significantly less degree than are those of deteriorated patients. Epilepsy occurred in only one of 342 children born to 163 extramural patients with the same disorder. Infantile convulsions occurred in six of these children. The deteriorated and nondeteriorated patients with epilepsy, it appears, show a distinct and significant difference in the relation of hereditary factors to their disorder. There are constitutional or inborn differences between mentally deteriorated and nondeteriorated epileptic patients. Not only are there important clinical differences between the mentally normal person with epileptic seizures and the psychotic epileptic, but the differences in hereditary background and in native or constitutional makeup suggest the existence of a fundamental distinction between these two groups of patients.

Sudden Death.—Sudden death in an apparently healthy individual or unexpected death in an individual known to be chronically ill raises many medical and legal problems. Markowitz explains that the primary medical problem is easily solved if sufficient anatomic changes are found which justify a cause for sudden death. There are instances, however, in which necropsy fails to reveal such anatomic justification. Yet testimony is constantly being given by physicians and lay coroners who have little or no information on the subject. The primary legal problem depends entirely on the medical observations. Probably the most common anatomic changes in these cases refer to the heart. Coronary changes are of extreme importance in cases of sudden heart death. There are coronary arterial changes, such as calcified and atheromatous plaques, which cause narrowing of the lumen but no occlusion; in these cases it is difficult to give an anatomic cause for sudden death. In syphilis the coronary arteries are but little involved but the aorta is puckered to such a marked degree that it may produce sudden

death by occlusion of the mouth of the coronary artery. Syphilis as an entity may be blamed for sudden death in other instances such as rupture of the aorta or cerebral vessel through a syphilitic aortitis or rupture of a syphilitic aneurysm. Aneurysm is one of the most common complications of syphilitic aortitis, especially in Negroes, in whom it is found twice as often as in the white race. Next to the heart, the brain is probably the most frequent seat of anatomic changes which produce sudden death. Sudden deaths due to pulmonary disturbances or edema of the larynx are often encountered but rarely without history of some previous disease. Pulmonary embolism, a definite anatomic observation in explaining sudden death, usually follows some operative procedure or history of thrombophlebitis. Fat embolism following fracture may cause sudden death, sometimes occurring many hours after the patient is in apparently good condition. It is questionable whether air embolism, which is so often feared, is ever a cause of sudden death. In all cases of pulmonary and laryngeal deaths the history of the antecedent illness is of extreme importance. In cases of shock, whether anaphylactic or surgical, anatomic evidence of death is difficult to demonstrate. The mechanism of death is unknown; the theoretical explanation of a neurocirculatory disturbance bears some weight in view of the minor injuries and even emotional distress which may precipitate shock. Sudden death may occur of an individual who has been on a prolonged drinking spree. The history in these cases usually indicates chronic alcoholism and anatomically the essential signs are extreme fatty degeneration of the liver with varying degrees of cerebral edema. Death is most likely due to hepatic insufficiency.

Vitamin C in Lead Poisoning.—After physical examination of 400 men exposed daily to lead, Holmes and his colleagues made monthly checks on the basophilic aggregation of the blood smear and on the degree of stippling. Records of these monthly tests were kept throughout the year of observation. During the last three months of this period weekly tests were recorded on a cooperative group of thirty-four men, all of whom had symptoms and showed signs of chronic lead poisoning. In these men differentials were also recorded on the Wright smear. From April 1937 to Nov. 15, 1937, from 80 to 100 grains (5.2 to 6.5 Gm.) of the gluconate, lactate and diphosphate salts of calcium were given to these thirty-four men. In addition, vitamin D (940 units) and vitamin A (9,400 units) were given daily. The observation was made that the symptoms and signs exhibited by these men were similar to those found in subclinical scurvy. Ascorbic acid (100 mg. of vitamin C daily) oral therapy was instituted in the group of thirty-four patients with chronic lead poisoning: seventeen were given ascorbic acid alone (at least two months after discontinuing the calcium salt injections), while the others continued the calcium therapy and at the same time took tablets of ascorbic acid. In general, the first group of patients showed a marked improvement in vigor, cheerfulness, color of skin and blood picture. In a week or less after beginning the treatment most of the men enjoyed normal sleep, lost the irritability and nervousness so common with high calcium treatment of lead poisoning, enjoyed their food more, and no longer had tremors (if observed before). Several cases

of leukopenia (probably due to previous prolonged calcium therapy) were cured by the ascorbic acid treatment. In the second group the gain was less marked and rather irregular. There was no gain in the number of mature neutrophils in the blood, in strange contrast with the rapid gain when ascorbic acid alone was given. In several instances alcohol nullified the good effects of calcium as well as of ascorbic acid, a complication that workmen exposed to lead hazards would do well to avoid.

Normal Hematologic Standards in the Aged.—In determining the normal hematologic standards of 160 men more than 60 years of age, Miller found that the erythrocytes per cubic millimeter of blood are diminished in old age. The average erythrocyte count is 4,460,000. Chronic low grade infection, nephrosclerosis and decreased cellularity of the red bone marrow in old age may be causative factors. Hypertension did not produce an increase in the erythrocytes. The hemoglobin per hundred cubic centimeters of blood is decreased in the aged, the average being 14.3 Gm. The decrease in hemoglobin is proportional to the decrease in the erythrocytes. The leukocytes and differential counts are within normal limits.

Treatment of Lobar Pneumonia with Sulfapyridine.—Cutts and his associates state that of the eighty-four patients with lobar pneumonia treated at the Rhode Island Hospital during the past winter only twenty-two were treated only with serum, forty-four were treated with sulfapyridine alone, thirteen with serum and the drug and five, entering the hospital after the fifth day of their disease, received no drug or serum therapy. Patients given both the drug and serum were not chosen because of any greater severity of their illness. Severe pneumonia was present in all groups in about equal proportions. Analysis of the duration of the disease at the time of admission showed that those in the serum-treated group averaged 2.4 days while those treated with the drug alone averaged 3.2 days. In the group of patients receiving combined treatment the average duration was two days. The average age of the drug treated patients was 42 and the age of those who were serum treated was 43, while those receiving both serum and the drug averaged 50 years. There was one death among the patients receiving sulfapyridine alone, three among those treated with serum and the drug, two of the serum treated patients died and three of the five patients admitted to the hospital after the fifth day of illness and receiving no treatment died. The authors made an attempt to grade all cases as to the therapeutic response, taking into consideration the number of lobes involved, the day of the disease when treated, blood cultures, age of the patient, type of infecting organism, temperature response and presence of complications. According to this classification 90 per cent of the drug treated cases yielded good results, as compared to 73 per cent of the serum treated group. From their results the authors infer that at least in the great majority of cases sulfapyridine exerts no serious toxic effects if used in the dosage described. How-

ever, nausea and vomiting were quite troublesome. The occurrence of both rash and drug fever in the two patients receiving more than 40 Gm. of the drug suggests that these large doses should be used with caution. Agranulocytosis or acute hemolytic anemia was not encountered, but their known occurrence in occasional cases makes frequent blood counts and close observation essential. In the authors' experience sulfapyridine was equally effective in all types of pneumonia, with the exception of that caused by the type III pneumococcus.

Gastrointestinal Allergy.—Lintz discusses a class of patients (472) suffering from various digestive disturbances who are incapacitated and yet not sick enough to go to bed. Incompletely digested foreign proteins gain access to the circulation not only in these patients but in almost every one. These proteins are merely the exciting agents that set off the patients' cells which inherently react in an abnormal manner. For instance, the symptoms of asthma are always the same, irrespective of the agent producing it. The author is of the opinion that these patients lack or are deficient in a certain poison neutralizing ferment, transmitted according to laws of heredity, which normal people possess. He is convinced that the only difference between normal people and allergic people is one of degree. The nonallergic person can simply tolerate larger doses of the allergens. While 10 per cent of the population suffers from major allergy, more than half of us manifest mild and infrequent allergic symptoms at one time or

another. Who does not know of some food or other substance that gives him clogged nose, sneezing spells, colds, coughs, dyspnea, headache, rashes, itching, suggestive mild hay fever, asthma, migraine and cutaneous allergy? Of all the manifestations of allergy the author states that he finds the gastrointestinal form by far the most frequent. This is to be expected in view of the fact that allergens act mainly on the unstriated muscle cells, the vascular and the autonomic nervous system and the secretory glands. The history is by far the most important point in the diagnosis and treatment of these patients. There are three phases to this factor: 1. The patient usually presents other allergic manifestations. 2. A family history of allergy will usually be found. In 70 per cent of these cases the family history was positive for allergy. 3. History of attacks attributed to allergens is almost always elicited. The autonomic nervous system plays a most important part in the production of gastrointestinal allergy and explains its apparent vagaries as to why a patient can tolerate a food at one time and not at another. It is overstimulation of the vagus that is chiefly concerned with allergy, for the vagus causes increased secretion, spasticity, excessive mucus formation, colic, hyperirritability and increased vascular permeability, which sequence of events occurs in allergy. The plurality of digestive complaints and the dominance of the nervous symptoms are suggestive of allergy. It is suggested that herpes occurring in the stomach and duodenum and its digestion is responsible for certain peptic ulcers. Nonbeneficial operations of all sorts should arouse a suspicion of allergy. The history and symptoms are more reliable than the dermal tests. Coffee not only produces allergic symptoms but makes patients more susceptible to other allergens. A spastic intestine is responsible for hemorrhoids. Organic disease should be ruled out and allergy should be made as the last diagnosis.

Closure of Patent Ductus Arteriosus.—Gross and his colleagues report the case of an 11 year old boy who had typical physical and x-ray signs of a patent ductus arteriosus. As the child had been followed over a period of several years,

there had been slight but definite hypertrophy (or dilatation) of the heart, this change being presumably caused by the large shunt between the aorta and the pulmonary artery. In the attempt to reduce the work of the heart imposed by the shunt and also to lessen the danger of subacute bacterial endarteritis, surgical exploration was undertaken for obliterating the ductus. The vessel was found to be from 11 to 12 mm. in diameter and was successfully ligated. The patient stood the operative procedure with extremely little reaction. This is the second case to be reported.

Bleeding Tendency and Vitamin K.—Olson and Menzel determined the plasma clotting time of twenty-four patients with obstructive jaundice. Twelve of the patients were considered to have bleeding tendencies because of abnormally prolonged plasma clotting times. The other twelve had normal plasma clotting times, though three bled after operation and in two of these cases the plasma clotting time became markedly prolonged before bleeding occurred. These fourteen patients were treated preoperatively with vitamin K concentrates and bile salts. All but one patient had marked improvement of the plasma clotting time. Seventy-five per cent of the patients with bleeding tendencies, but not treated with vitamin K, bled postoperatively, whereas only 36 per cent of those treated with vitamin K had postoperative bleeding complications. No patient had serious bleeding while receiving treatment. Since vitamin K and bile salts decrease the bleeding tendency in obstructive jaundice, their use is recommended in all cases of jaundice both preoperatively and postoperatively.

Conservative Surgery with Irradiation in Gas Gangrene.—According to Sewell, in the seven years prior to 1935 twelve cases of clinical gas gangrene of the extremities were seen at the Strong Memorial Hospital. In four of these gangrene developed in the stump following amputations for other causes. In the other eight cases, on recognition of the infection, immediate amputation was advised and performed except in one instance, in which it was refused. This patient received only a small amount of serum and lived; while, of the remaining seven, four died on an average of twenty-four hours after the therapeutic amputation. In the following eighteen months, with the introduction of roentgen therapy and sulfanilamide, of five patients with both clinical gas gangrene and positive cultures, two died, both aged men. One had severe diabetes and lived for three days after a midhigh amputation. It is regrettable that more reports concerned with irradiation in gas gangrene have not appeared in the general surgical journals, for, although most roentgenologists are well informed of the merits of this mode of therapy, it has not been brought sufficiently to the eyes of the general surgeon. Since the introduction of irradiation and sulfanilamide, it has been amply shown that the infection can be controlled and cured without amputation and even without surgery in numerous cases in which, several years ago, immediate operation would undoubtedly have been performed.

Acute Hyperparathyroidism.—Oliver suggests that the clinical syndrome including vomiting, loss of weight, anorexia, bone pains, constipation and lassitude, all of them recently exacerbated, with increasing drowsiness, evidence of fever, disproportionate tachycardia and impaired renal function without hypertension should prompt a careful examination of the neck for a parathyroid tumor, estimation of the serum calcium and phosphorus and x-ray study of the kidneys. From the experiments of several investigators it appears clear that the ill effects may be reversible and that, if suitable fluid and electrolyte replacement is carried out and followed by removal of the tumor, good results may be expected; therefore recognition of the condition and its speedy confirmation by investigation are of considerable importance. Two cases of parathyroid chief-cell adenomas are reported and it is believed that they constitute examples of a clinical syndrome—acute hyperparathyroidism—which, if recognized, is amenable to therapy.

Effect of Sulfonamide Derivatives on Blood Serum.—Scott and Meerapfel describe two cases in which treatment with a sulfonamide derivative over a long period and in large doses (423 grains [27.5 Gm.] of uleron [dimethyl disulfanilamide] in one case and 748 grains [48.6 Gm.] of sulfanilamide in the other) was followed by an alteration in the blood serum which precluded the finding of a suitable donor for blood transfusion. Normal serum treated in vitro with sulfanilamide for four days or more agglutinated the red blood cells of donors of the corresponding blood group and the cells of universal donors. When these drugs were administered over shorter periods and in smaller doses to six other patients, such a change in the blood serum did not take place.

Insulin Premedication in Convulsion Therapy.—The resistiveness, panic and fear accompanying convulsion therapy have been eliminated by Sands with insulin premedication of twenty-two of twenty-three schizophrenic patients. The insulin premedication has enabled him to complete convulsant treatments of the twenty-two patients which would otherwise have had to be terminated prematurely because of resistance and apprehension. In the instance in which treatment was stopped it

was done because of the excessive exacerbation of symptoms on recovery from each convulsion. The patient's condition deteriorated and it was considered inadvisable to continue the treatment. The high proportion of "negative fits"—30 per cent—which these resistive patients had without insulin was reduced to 13 per cent with insulin. There have been but three patients discharged and one has since relapsed. This is an inferior figure compared with most of the published statistics and those of Claybury, the discharge rate being 42 per cent. This use of insulin, by greatly diminishing the unpleasantness of convulsion treatment to resistive schizophrenic patients, has facilitated their nursing and management. The object in insulin premedication is to give such a quantity as will induce the patient to cooperate with the injection of a convulsant drug. The dose may require pushing until drowsiness and languor supervene. On almost every occasion the induction of the fit has been sufficient to dispel any lethargy induced by the insulin. The patients are given sugared tea to drink as soon as the convulsion is over. In two cases, owing to the development of insulin sensitivity, recovery was effected with dextrose solution through the nasal tube on one occasion and with intravenous dextrose on two other occasions. As with metrazol therapy, the management of the premedication can be performed by the ordinary nursing staff of the mental hospital without the usual special training generally necessary for insulin shock therapy.

Immunization Against Smallpox and Typhoid.—In order to test the efficacy of the combined active immunization against smallpox and typhoid, Yaoi and his associates vaccinated at three weekly intervals 7,054 unselected young adult technicians of the heavy metal industry and a few office workers with freshly prepared heat killed phenolized typhoid vaccine. However, only 74.81 per cent of this number received the three injections. The main complaints expressed by the evaders was fever, headache or malaise, besides reddening, swelling and pain, the severe local reactions. The ill effects which may be caused by the combined active immunization by means of the purified vaccine virus and typhoid vaccine were determined in 838 newly admitted technicians. Only the first of the three doses contained a mixture of purified vaccine virus and typhoid vaccine. Ill effects which appeared to be more severe than when typhoid vaccine alone was used were not observed. It was confirmed that the two antigens used acted quite independently in that nodules due to the vaccinia virus appeared on the fourth or fifth day, after the immediate local reaction subsided. From a study of the local reactions caused by the typhoid vaccine and the combined immunization the authors find that the allergic reaction caused by the typhoid vaccine is much more severe than that caused by the smallpox vaccine. After combined active immunization, serums drawn on the fifteenth day showed titers from 1:1,600 to 1:3,200 and in those drawn on the twenty-second day the titers ranged from 1:3,200 to 1:6,400. Thus it was decidedly confirmed that more rapid and effective immunization can be obtained by the combined method than in the case of typhoid vaccination alone. The comparison with two agglutinin figures after seventy-five days clearly demonstrated the superiority of the combined method (titers from 1:800 to 1:1,600) as compared with typhoid vaccine (titers from 1:400 to 1:800) with regard to the duration of immunity.

B₁ Avitaminosis and Cardiac Insufficiency. L. Langeron.—p. 1189.

*Interpretation of Examination of Labyrinth in Aviators. W. Salem.—p. 1191.

Examination of Labyrinth in Aviators.—Salem says that at the otorhinolaryngologic clinic of the school of naval aviation in Rio de Janeiro they have about 200 records pertaining to examinations of the labyrinth of aviators. In the course of these examinations and of continuous control tests on aviators it was found that life as an aviator rapidly fatigues the organism and influences the vestibular apparatus. The more active the man is as a pilot, the weaker become his vestibular reactions. The rotatory test of Bárány is employed by the author only during the first examination; for experienced aviators he found the test of little value. He observed that the postrotatory nystagmus should not be interpreted by algebraic formulas and he gained the impression that it is advisable to adhere to the general medical principle that an isolated sign never has absolute value. The falling test, with the head inclined 90 degrees forward, he found of no clinical value, but he regards the caloric test as the best mode of examination of the labyrinth. He cites cases of hypo-excitability in experienced pilots and says that to him such hypo-excitability is of no clinical value. If such pilots have no other symptoms, they can continue their activity as aviators. The aviator acquires a sense of equilibrium superior to the normal. Aside from this, the labyrinthine sensitivity is nearly always diminished; this seems to be a phenomenon of adaptation. By itself hypo-excitability does not reveal a perturbation of the labyrinth and has no value in aviation. The author also mentions a case of labyrinthine hyperexcitability detected by caloric tests in a stunt flier. This man was permitted to continue ordinary flying but was advised not to do stunt flying and high altitude flying. On the basis of his observations the author reaches the following conclusions: 1. There exists a labyrinthine adaptability in aviators which modifies the reactions in the examinations on the vestibular apparatus. It is a relative modification and of no pathologic significance in aviation. 2. The labyrinthine hypo-excitability or hyperexcitability cannot be given uniform interpretations, but they must vary relatively in each case and in relation to each form of flying.

Therapeutic Significance of Elimination of Calcium Acetyl Salicylate Which Lasts More Than Twelve Hours. F. Dellamartina.—p. 742.

Experimental Contribution to Blood Transfusion on Battle Fields. H. Knoll and H. Märki.—p. 744.

Creatinuria in Deficiency of Vitamin E.—Verzar says that creatine or creatinine originates in the endogenic muscular metabolism and also is taken in with the food, and that some investigators maintain that it develops also from arginine. Creatinuria is observed in different disturbances of the glycogen metabolism of the musculature but also in some endocrine disturbances. It has been observed in connection with hyperfunctioning of the anterior lobe of the hypophysis, in pregnancy and in hyperthyroidism. Moreover, in animals the administration of anterior hypophyseal and of sex hormones has been known to produce an increase in the elimination of creatine and a decrease in that of creatinine. Postlimatectic creatinuria has been suppressed by the administration of androgen. All these observations indicate that creatinuria may be elicited by reduction in the production of sex hormones or by disturbances in the anterior lobe of the hypophysis. New light was thrown on the problem of muscular dystrophy by the observation that certain diets elicited muscular dystrophy but that they failed to do so when they were complemented by wheat germ oil with its high vitamin E content. The author cites his own observations on the creatinuria of rats with muscular dystrophy, which were fed for a number of months with a diet lacking vitamin E. He further shows that it was possible to counteract the creatinuria of animals with muscular dystrophy by means of a synthetic vitamin E (dl-alpha-tocopherol acetate). He found that whereas the daily administration of 50 mg. of this synthetic vitamin E

produced some effect in the animals, 200 mg. daily was required to produce normal creatine values. The large quantities of synthetic vitamin E that are required for cure are surprising, because only small quantities of vitamin E are necessary to achieve a prophylactic effect. Experiments with synthetic vitamin E revealed that it effects fixation of creatine but that this fixation ceases as soon as does the administration. Regarding the point of attack of vitamin E in the organism, the author says that in 1930 he advanced the theory that it is in the anterior lobe of the hypophysis. He summarizes his discussion by stating that creatinuria is a result of a disturbance of the muscular metabolism on the one hand and of the reduction of the secretions of the anterior lobe of the hypophysis and of the sex glands on the other hand. The function of these two systems is impaired in case of deficiency of vitamin E. The administration of a synthetic vitamin E counteracts the dysfunction of both systems as well as their chief symptom, creatinuria, in that it effects fixation of creatine in the tissues.

Elements of Diagnosis in Tuberculosis of Infants. T. Villedor.—p. 363.

*The Lung in Whooping Cough. R. Mendoza and J. Mir.—p. 399.

The Lung in Whooping Cough.—Mendoza and Mir carried out a clinical and x-ray study in a group of eleven children who had whooping cough. They found that, when the condition is benign, fever and physical signs of involvement of the respiratory tract do not appear and the respiratory tract appears normal on x-ray study of the chest. When fever and physical signs of involvement of the respiratory tract appear, the respiratory tract shows abnormal x-ray shadows of various extent and intensity, which disappear in about a week as fever abates and the physical signs of the respiratory tract disappear (unless complications occur). The tuberculin tests are (or become) negative in the course of whooping cough and remain negative after recovery of the patient. As a rule the abnormal x-ray shadows are located at the infra-hilus and juxtamedialastinal regions. Regularly they are bilateral and triangular, from the base (or else diaphragm or mediastinum) to the apex (or else the hilus) and may overshadow the hilocardial space. The transparency of the pulmonary fields is diminished in some cases. According to the author, the clinical evolution of the condition, the physical signs and the roentgenogram show that the alterations of the respiratory tract in whooping cough are due to general inflammation and cellular infiltration of all segments of the tract with early involvement of the bronchi, bronchiole and lung and the development of a consequent latent exudative pleuropulmonary condition which may evolve to different types of pneumonia, pleurisy or bronchopneumonia. That the infiltration is not of a tuberculous origin is proved by the following facts: (1) The patients do not have a history of tuberculosis, (2) the tuberculin tests are negative, (3) the symptoms, physical signs and x-ray alterations are of short duration and (4) the topography and character of the shadows do not show tuberculosis. The author believes that the role of whooping cough for the development or else aggravation of tuberculosis has been exaggerated. The negativity of the tuberculin tests in the course of the infection and after it (in cases of previous positive tests) do not necessarily indicate evolution of tuberculosis. He calls attention to the importance of a differential diagnosis between whooping cough and certain forms of spasmodic cough from tuberculous tracheobronchial adenopathies which may be erroneously diagnosed as whooping cough.

Blood Pressure Regulation in Addison's Disease.—Thaddea reviews the clinical and experimental observations of other investigators on the blood pressure behavior and regulation of persons with Addison's disease, before and after treat-

ment with adrenal cortex extract. Systolic pressure values as low as 50 mm. of mercury and lower are not uncommonly found in Addison's disease, with diastolic values somewhat better. Persons with tuberculosis of the adrenal glands are said to show a somewhat higher pressure than those proved at necropsy to be without it. Patients with cardiac compensation are not affected by adrenal cortex extract; those with cardiac decompensation have an increase of systolic and diastolic pressure range after similar therapy. In Addison's disease, blood pressure is highly dependent on the position of the body, as tested with a tilting table and the measurement of patients during physical exertions such as standing, knee bending and leg raising. Patients with Addison's disease not therapeutically managed have an insufficiency of blood pressure regulation that may lead to collapse. Dysfunction of the regulatory mechanism may be due to "hypotonic" or "hypodynamic" disturbance. In the former, diastolic pressure in the upright position remains the same or rises; in the latter, diastolic pressure in the same position shows a decrease simultaneously with the systolic. Such "hypodynamic" regulatory disturbances are conditioned by the fact that vasoconstriction compensatorily necessary in the upright position fails to occur because of the absence of nerve impulses. "Hypodynamic" dysfunction may occasionally combine with "hypotonic." The cause of these regulatory fluctuations must be sought in the functional unity of the hypophysis (anterior lobe) and the adrenal cortices. However, the dysfunction of the "central intercalary areas" may be involved rather than the varying degree of excitability in the peripheral pressoreceptor system. Hypodynamic regulatory disturbances were found to yield to long continued treatment with adrenal cortex extract and no longer manifested low pressure as before treatment when put to the test of the physical exertions already mentioned. The author stresses the significance of the circulatory conditions in insulin shock. Insulin intravenously administered precipitated rise of blood pressure of patients with normal tone in the second phase of insulin intoxication and is usually coincident with the lowest level of the blood sugar curve. In persons with Addison's disease not under therapeutic supervision sudden rise of blood pressure was not observed. According to the author, a further circulatory symptom of adrenal insufficiency is the almost regular absence of the otherwise demonstrable pressure increase after administration of epinephrine. This dysfunction, however, is susceptible of correction by adrenal cortex extract or hydrochlorate cysteine therapy.

Removal of Liver Lobe for Alveolar Echinococcus.—

According to Danilov the alveolar echinococcus of the liver bears a certain resemblance to a malignant growth because of its infiltrating character, its iron hard consistency, adhesions to neighboring organs, formation of metastases in the brain, pleura, lungs, endocardium and the lymph nodes of the liver hilus, and its tendency to recurrence after radical removal. The alveolar echinococcus develops slowly and as a rule is diagnosed late. The average duration of life of a patient with this condition is about eight years. There were admitted in the last two years to the Bashkir Medical Institute fifty-seven cases of echinococcus of the liver, twenty-five of which were of the alveolar or multilocular variety. In two of these operation was refused and in sixteen the intervention was limited to exploration, while in seven a radical removal was performed. In one case the author removed the entire left lobe of the liver, the seat of a large echinococcus cyst, together with a growth invading the right lobe. There was considerable traumatism and loss of blood leading to shock, requiring two blood transfusions to combat the shock. The patient recovered.

Allergic Etiology of Catarrhal Icterus.—Brouwer discusses the connection between "serous inflammation" and disease of the liver. He says that Eppinger regards catarrhal icterus as a serous hepatitis which is closely connected with alimentary intoxication and that Swedish physicians assume that it is an infectious disease. This infectious theory is corroborated by the occasional epidemic appearance which the author was able to observe in Batavia. However, the demonstration of a specific causal factor has not been successful as yet and recently an allergic etiology has been considered. The author describes two cases of catarrhal icterus in which the prodromal symptoms were of the allergic type; in one case the catarrhal icterus was preceded by the cutaneous rheumatismal syndrome and in the other case by severe attacks of migraine. He thinks that the eosinophilia which existed in both cases indicates the allergic character and that the migraine as well as the urticaria and articular disturbances can be regarded as equivalents of gastro-enteritis. They indicate humoral disturbances of the type existing in serum disease which first involve the skin, the joints and nervous system and which secondarily involve the liver. The author cites several other investigators who suggested a connection between anaphylaxis and icterus.

Postvaccinal Encephalomyelitis.—Brouwer demonstrates that the incidence of postvaccinal encephalomyelitis is decreasing in the Netherlands because the frequency of vaccination has decreased. In 1938 three cases of encephalomyelitis were accepted by the Governmental Committee for Encephalitis as postvaccinal in origin. Two of these were studied microscopically. Typical areas of demyelination with perivascular increase of microglia cells were found scattered through the entire central nervous system. These histologic changes are a constant manifestation in the postvaccinal form of encephalomyelitis but they do not exclude other forms of encephalitis, because they can be found also in other postinfectious encephalitides. The author emphasizes that the formerly widely accepted belief that patients with postvaccinal encephalitis either succumb or recover without residual defects is not correct in that cases have been observed in which tetraplegia or other forms of invalidism persisted many years later. As regards the pathogenesis, the author does not accept the theory of activation of a virus already present in the central nervous system before vaccination. He believes that the encephalitis is caused by the vaccinia virus itself but that an endogenous factor is to be considered.

Prognosis of Pulmonary Tuberculosis in Children.—Holm reports a study of the prognosis of active pulmonary tuberculosis in children. Of 267 children, fifty-one died. In forty-six of these tuberculous meningitis or miliary tuberculosis was the direct cause of death; the other five died as the result of the pulmonary process. In forty-eight of the fifty-one fatal

cases, death resulted within one year after the admission to the hospital. Thus it seems that, if the children outlive the first year of illness, they have a good chance of surviving. The prognosis differs greatly in the various age groups. Of fifty-five children under 1 year, twenty-four died; of fifty-six children aged from 1 to 2 years, fourteen died; of forty-one children aged from 2 to 3 years, five died; of eighty-five children aged from 3 to 7 years, seven died, and of thirty children aged from 7 to 14 years, one died. On reexamination of 216 survivors, only nine were found who were still ill. This indicates that if the children survive the first year of illness they stand a good chance of recovering completely. As roentgenography is considered the most important method of examination, particular efforts were made to elucidate what prognostic conclusions may be drawn from the roentgenogram at the onset of treatment. Tables indicate that the extension of the tuberculous processes in the lungs is decisive in the prognosis, while the location of the processes has no demonstrable significance. Nineteen patients had miliary dissemination in both lungs; seventeen of these patients died while two recovered completely. Thus cases of this form of tuberculosis are not to be considered altogether hopeless. Exudative pleurisy was found in fifteen children; none of them died. All children were tuberculin positive. The sedimentation test proved to be of but slight prognostic value. Auscultation and the subjective symptoms provided no information that was of prognostic value. *Extrapulmonary complications were rare and they appear not to aggravate the prognosis. In 167 cases it was possible to establish the source of infection, and it was intrafamilial in 120 of these cases. For children over the age of 1 year the prognosis appears not to be less favorable in those cases in which the source of infection is known or even intrafamilial.

Hemorrhagic Diatheses.—Von Willebrand and Olin state that in true hemorrhagic diathesis the hemorrhages are the expression of injuries which affect the whole organism or a certain organ in its entire extent and that they seem to occur spontaneously or after insignificant traumas without establishable more marked exogenic injuries. Etiologically the following types are distinguished: avitaminosis, hemorrhagic diathesis in general, disturbances in nutrition, hereditary types, infectious types, toxic types and hemorrhagic diathesis in diseases of the blood. In the origin of hemorrhagic diathesis a number of different factors are important, namely the blood chemistry, the form elements, especially the thrombocytes, together with the mechanism of bleeding and arrest of bleeding of the vascular walls. In the group of pseudohemophilic disorders four different types have been differentiated: hereditary hemorrhagic thrombasthenia (Glanzmann), constitutional thrombopathy (von Willebrand-Jürgens), the Naegeli type (Switzerland) and the Jürgens type (central Germany). These four types are united in a group termed hereditary thrombopathies. Common to the group are heredity, dominant transmission and deficiency of the thrombocytes together with the vascular weakness found in all hemorrhagic diatheses. To aid in diagnosis, six different types (Jürgens) may be set up: the avitaminotic, the hemophilic, the thrombopathic, the thrombopenic, the capillary toxic and the hormonal type of hemorrhage.

*Serologic Studies in Acute Pneumonia. G. Löfström.—p. 1927.

Serologic Studies in Acute Pneumonia.—Löfström says that by the use of mixed vaccines and a slide agglutination method the specific agglutinins against the thirty types of pneumococci can be studied easily. His material comprises eighty-seven cases (thirteen serum-treated cases of lobar pneumonia, twenty-eight additional cases of lobar pneumonia, thirty-eight of bronchial pneumonia, seven of acute infections of the upper respiratory passages and one case of acute tuberculous pneumonia). In eighty-two cases pneumococci were established and type determined and in fourteen cases streptococci were demonstrated, which in eleven cases occurred together with pneumococci. In two cases examination of the sputum was bacteriologically negative. In forty-two of the seventy-four non-serum treated cases agglutinins appeared, occurring with great regularity in lobar pneumonia and with less regularity in bronchopneumonia and infections of the upper respiratory passages. In about two thirds of the cases only one type of pneumococcus was found, and homologous agglutinins developed in the majority of these. Agglutinins not corresponding to the pneumococci occurred in four cases. In about one third of the material more than one pneumococcus type was present. In all these cases there were agglutinins against only one type. In three cases there were specific agglutinins without any established pneumococci. Specific agglutinins against pneumococci are not found in the population in general. During a barracks epidemic agglutinins were established in nine of twenty-three carriers (Gard and Löfström). In acute pneumonia, agglutinins develop between the fifth and the twelfth day. In five of the six fatal cases, agglutinins did not develop. In cases treated with sulfapyridine, agglutinins developed as in untreated cases. In the thirteen cases of pneumonia in which serum treatment was given, the highest titer was usually established on the day after the treatment; in the ten cases treated during the first days of the disease the titer rapidly diminished and disappeared. In the nine bacillary carriers with positive agglutinins and in five of the seven type I pneumonias and one of two type II pneumonias, agglutinins were still present after from three to four months. Under certain conditions antibodies occur in the blood serum which cause swelling of the capsules of types XXVII and XXVIII, sometimes also of types IX, X, XVI, XVII, XVIII, XXI and XXIII. They are best studied by the use of a dilution of the vaccines about twenty times greater than in the regular slide method. Agglutination occurs when the swelling is most pronounced. Unspecific capsule swelling seems to occur regularly in pneumonias, less regularly in infections of the upper respiratory passages. The reaction was not positive in 120 healthy young recruits. During an epidemic of acute respiratory infection the reaction became positive in about one third of 157 soldiers. Complications developed chiefly in the cases with positive capsule swelling reaction. In the group with fever above 39 C. (102.2 F.) complications occurred twelve times in the 36 per cent with positive reaction as against once in the 64 per cent with negative reaction. In eighteen cases of lobar and bronchial pneumonia the reaction was positive in the first blood specimen, that is on the first to the seventh day of the infection. In the twelve cases in which the course was uneventful the reaction became negative between the sixth and the twelfth day; in the other cases, in which the reaction remained positive, pleuritic exudate and serum sickness developed and four of the cases were fatal. The reaction does not seem to be identical with the intracutaneous test of Abernethy and Francis.

THE POSTOPERATIVE CARE OF THE URINARY BLADDER

J. DONALD WOODRUFF, M.D.

AND

RICHARD W. TE LINDE, M.D.

BALTIMORE

Every one with any surgical experience will agree that difficulties in voiding play a major role in postoperative discomfort. The closer the field of operation approaches the bladder region, the greater the difficulty in voiding spontaneously and the greater the discomfort from overdistention. Hence, the postoperative care of the bladder concerns the gynecologist more than any other surgeon. In recounting their hospital experiences, patients frequently mention the discomfort from overdistention or from catheterization among their most unpleasant memories. There is, however, an even more important reason than the patient's comfort for the proper handling of the bladder after operation. Many chronic and serious urinary tract lesions have their origin in mismanagement of the bladder at this time. In our experience in female urologic conditions we have been struck with the frequency with which patients date their illnesses from trouble in emptying the bladder after operation.

In 1925 a routine was established in the gynecologic service of the Johns Hopkins Hospital which had for its purposes the promoting of postoperative voiding and minimizing the use of the catheter. The procedure consists of the instillation into the bladder of 1 ounce (30 cc.) of 0.5 per cent aqueous solution of mercurochrome at the conclusion of the operation, while the patient is still on the operating table. Here sterile technic should be at its best as well as easiest. At the same time the patient is given rectally 1 liter of 2 per cent sodium bicarbonate solution containing 60 cc. of liquid petrolatum. This rectal instillation of fluids was borrowed from the clinic of the late John G. Clark of Philadelphia. It has for its purpose the insurance of a good alkaline fluid intake during the early postoperative period and the softening of the fecal material in the lower part of the bowel, which it is hoped will facilitate early defecation. It was also thought that an adequate early fluid intake would give the bladder "something to work on" in its early attempts at emptying itself. Whether the giving of this fluid by rectum has any beneficial effect in bringing about early micturition will be discussed later in considering the results of our experience. The originator of the idea that a

bladder instillation of mercurochrome might facilitate postoperative voiding is not known to us.

The favorable results of our early experiences were reported by Craig¹ in a western journal in 1930. As a result of this there has been an adoption of the procedure in some clinics on the West Coast, but generally it is little used. Our results over a long period have been so satisfactory in cases of pelvic laparotomy that we believe they should be brought to the attention of the general profession.

In 1914 Taussig² concluded from his study that the danger of infection from catheterization lay less in the technic than in urinary stagnation. Curtis³ has repeatedly emphasized that simple catheterization at times other than in the postoperative period is relatively harmless. Our experience confirms the views of both of these men. In our outpatient department and in private practice we pass catheters several times a day to obtain urine for diagnostic reasons. We have never had any reason to believe that this procedure has been responsible for a urinary tract infection. Our technic in the outpatient department is simply to swab the urethral meatus with two successive toothpick swabs dipped in 5 per cent mercurochrome. Because of the undesirable staining qualities of mercurochrome, we have substituted an aqueous solution of 1:1,000 merthiolate in the office with equally satisfactory results. With this technic the bacterial flora about the meatus is reduced, but we do not claim for it complete sterilization of the meatus and certainly not of the outer urethra. Undoubtedly some bacteria are introduced into the bladder, but in spite of this we have never seen cystitis occur. The ability of the patient to empty her bladder completely at subsequent voidings apparently prevents the development of cystitis. In dealing with the bladder postoperatively, one is confronted with the additional factor of residual urine. That there is practically always residual urine postoperatively, even when the patient voids from the beginning, has been well demonstrated by Taussig.² He compared the total amount of urine voided in a given time in a group of thirty who voided spontaneously with the total amount obtained by catheter in a group of thirty over an equal period. An average of 5 ounces (150 cc.) more of urine was obtained by catheter from each patient. That there is residual urine for a time in those patients who have required one or more catheterizations has been demonstrated innumerable times by all who practice catheteri-

Read before the Section on Obstetrics and Gynecology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

zation for residual urine after the resumption of micturition. Once one has catheterized a patient postoperatively and presumably introduced a few bacteria, it becomes important to prevent stasis of residual urine on resumption of voiding. We watch the patient carefully after catheterization; if the frequent voiding of small amounts or quickly recurring bladder discomfort after voiding of even larger amounts suggests residual urine we catheterize at least once daily until the residue is reduced to 50 cc. or less. Our experience in reducing the incidence of urinary tract infections by this routine has convinced us of its importance. However, all students of this subject admit the desirability of doing away with the catheter entirely if possible. Any procedure which makes a real advancement toward this end is worthy of consideration.

Most reports on methods of promoting voiding are concerned with inducing the bladder to empty itself after postoperative retention has occurred. The usual procedures of running water, putting warm water in the bedpan, giving enemas, irrigating the perineum and elevating the patient to a partial sitting position are known to all surgical nurses and physicians. They undoubtedly are of value, especially in those cases in which the psyche plays a large role. Drugs have been used extensively. Several years ago some rather enthusiastic reports appeared on the use of solution of posterior pituitary, but subsequent experience has proved disappointing. The parasympathetic stimulators doryl (carbaminocholine chloride) and mecholyl (acetyl-beta-methylcholine chloride) have been used widely with some success. Doryl was first used clinically by Schulze,⁴ who noted success in 80 per cent of a large series of patients with urinary retention after childbirth and gynecologic operations. Subsequently the drug has been used in England⁵ and in this country with considerable success. Constitutional disturbances such as sweating, fainting, salivation, vomiting and a drop in blood pressure are noted in about one third of the cases. The writers on the subject do not consider these symptoms alarming. In our clinic we have had a limited experience with mecholyl administered by mouth in a dose of 25 mg. and we have had some success. We have seen no serious constitutional effects. Administered hypodermically, however, we feel that it is dangerous and the alarming constitutional effects far outweigh the beneficial effects in promoting voiding. In two instances we have been greatly alarmed by the sudden onset of profuse sweating, salivation, fainting, involuntary urination and defecation and a marked drop in blood pressure. In another institution in this city the hypodermic administration of 25 mg. of mecholyl resulted in death before the antidote of atropine could be administered.

The injection of irritants into the full bladder has been used to induce voiding. Baisch⁶ advised the injection of 20 cc. of 2 per cent boroglycerin solution into the full bladder, but Taussig² thought that this was responsible for cystitis in certain cases. Taussig² noted on doing air cystoscopy the not infrequent tendency of the bladder to contract as the air rushed in. He therefore tried the injection of several ounces of air into the full bladder as a mild vesical irritant and reported success in nine of eleven cases.

The method under discussion in this paper approaches the problem from a different angle. Our procedure is an attempt not to empty the distended bladder but rather to prevent distention by inducing the patient to void early.

In our series there were 500 pelvic laparotomy patients who were given the mercurochrome bladder instillation and the fluid by rectum in the operating room. Six and six-tenths per cent of these patients required one or more catheterizations. In a control series of 257 patients with pelvic laparotomies, done at another hospital, 51 per cent required catheterization. In this institution the routine postoperative order was for eight hour catheterization if necessary, whereas in our group the order was for catheterization twelve hours after the operation, if necessary, and after this every eight hours. This difference in orders, however, affected the time of first catheterization very little, for in the control group the average time after operation at which the first catheterization was done was ten hours and twenty-four minutes, whereas in our group it was ten hours and fifty-three minutes. The percentage of catheterizations in the control group is considerably higher than in many series reported in the literature, but both of our groups represent, for the most part, extensive pelvic laparotomies. The conclusion seems to be justified that catheterization has been reduced in our series to almost one eighth by this simple procedure.

We attempted to determine what effect the administration of fluid by rectum had on postoperative voiding. We were able to collect records on only fifty-four cases of laparotomy in which the bladder instillation was given but the fluid by rectum omitted. Five and six-tenths per cent of the patients required catheterization. Although this series is small we believe that it indicates that the essential part of our procedure is the bladder instillation; although we feel that the fluid by rectum is desirable for other reasons, we do not believe that it facilitates voiding.

The time and amount of first voiding in our laparotomies are interesting and instructive. For 551 laparotomy patients who received our routine treatment, the average time of the first voiding was five hours and thirty minutes. For the control series of 132 patients, who did not receive this postoperative treatment, the average time of first voiding was nine hours and twenty-six minutes. For a series of 495 patients receiving routine treatment, the average amount of the first voiding was 194 cc. whereas for a control series of 125 patients, who voided without catheterization and without treatment, the average amount was 168 cc. These data seem to show that by means of this routine the patients more completely emptied their bladders, for in five and one-half hours more urine was obtained than was voided in almost double the time by a control series. Considering the importance of complete emptying of the bladder in relation to the prevention of urinary infection, we believe that this accomplishment is a strong point in favor of our procedure.

The mode of action of the mercurochrome in promoting voiding has interested us; we believe it is due to a temporary chemical irritation of the bladder. Occasionally a little microscopic blood can be noted in the first specimen, but in only one case in our series was there gross hematuria. Often the patient calls for the bedpan as she is arousing from the anesthetic and complains of a marked desire to void before sufficient time has elapsed after operation to allow an appreciable amount of urine to collect in the bladder. The bladder

5. Maxwell, J. S.: *The Treatment of Postoperative Retention of Urine with Doryl*, *Lancet* 1:263 (Jan. 30) 1937. Moir, Chassar: *The Use of Doryl in Postoperative and Postpartum Retention of Urine*, *ibid.* 1:261 (Jan. 30) 1937.

6. Baisch, cited by Taussig.²

irritation usually disappears in twenty-four hours. Although the average first voiding is 194 cc., the amounts of subsequent voidings rapidly increase and we believe it is a reasonable assumption that complete emptying of the bladder is soon obtained.

The influence of the duration of the anesthetic confirms an impression which, we are sure, has been noted by most surgeons. We arbitrarily divided our laparotomy patients into two groups. In the first group, containing 227, the duration of anesthesia was less than one and one-half hours; 4.4 per cent of these required catheterization. In the second group, of 272, the duration of anesthesia was more than one and one-half hours and 7.4 per cent required catheterization. We were also interested in noting the effect on voiding of avertin with amylene hydrate as a basal anesthetic. In 280 cases in which this was used, supplemented by ether, 8.2 per cent of the patients required catheterization. In 217 cases gas, oxygen and ether were used and only 3.7 per cent required catheterization. It seems reasonable to suppose that the latter group recover more quickly from the anesthetic and hence are more acutely sensitive to the impulse to void. On the other hand, the avertin group are lethargic for most of the day of operation and hence less aware of their full bladders, which therefore require catheterization in a larger percentage of cases.

Although the postoperative comfort of the patient is of great importance to her, the avoidance of a persistent urinary tract infection is even more essential in the long run. We therefore made a study of our cases from that point of view. We sought to determine how many of our patients had evidence of cystitis on discharge from the hospital. In only one of the 500 cases was a bladder symptom present on discharge, and this consisted of only slight frequency but no burning. It was noted in the patient's history that she had had an attack of frequency and burning several years prior to admission, but her urine on admission was normal microscopically. Despite the symptoms just noted, the urine culture was negative on discharge.

Among the 500 patients who received our treatment, two developed pyelitis postoperatively, but in both cases there was a history of previous urinary tract infection. A short summary of these two cases follows:

CASE 1.—The patient complained of nocturia, having voided three to four times per night for two years, and of dysuria for three months before admission. The urine, however, was clear microscopically on admission, but no culture was made. On the third postoperative day the patient had a temperature of 103.2 F. and on the fourth day *Bacillus coli* was cultured from the bladder urine, which contained many white blood cells. On the fifteenth postoperative day the urine culture again showed *B. coli* but the patient had no symptoms. She was discharged on the twentieth postoperative day, still with a low grade fever. Twenty days later she returned to the hospital with typical acute pyelitis. She was treated with sulfanilamide and the urine became sterile. On discharge, after ten days of therapy, the patient was symptom free.

CASE 2.—On admission the patient gave a history of nocturia, voiding twice a night, and catheterized urine showed occasional dumps of white blood cells. The postoperative course was not remarkable and she had been allowed to walk. On the twentieth day she had a chill and a temperature of 104 F. The urine was loaded with white cells, and *B. coli* was cultured. The temperature became normal on the twenty-eighth day but the culture was still positive. Subsequent follow-up study in the dispensary revealed no residual urinary disturbance.

Here, then, are two cases of postoperative pyelitis and one of mild bladder symptoms in our series of 500

cases, but all three patients had histories of previous urinary tract infection. Let us compare these results with those of our control series of 249 laparotomy patients from another hospital. The postoperative history notes were less complete than in our series, so details such as notes on cultures and catheterized specimens were often lacking. However, in this group there were five cases of clinical cystitis and two of pyelitis. In none of these was there any evidence of preexisting urinary tract infection, but as before mentioned the histories were not as complete as those in our own series. Comparing these results with those of our own, we believe that we are justified in concluding that urinary tract infections are less frequent in patients treated according to our routine. In fact there was no postoperative infection in any patient who did not have a previous history of infection.

Our results with this procedure after the vaginal plastic operations were less successful. In fact our study shows that the procedure is of no value in promoting voiding after extensive vaginal operations. In our series of fifty-nine vaginal plastic cases, which includes twenty-five interposition operations, 58 per cent of the patients required catheterization. In our control series, in which patients did not receive our treatment, there were sixty-two cases, including twenty-eight interposition operations. Exactly the same percentage (58) of the patients required catheterization. Our clinical impression has been that the Watkins interposition operation offers the greatest difficulty with postoperative voiding. Our statistics bear out this impression, for after a total of fifty-three interposition operations in both series 72 per cent of the patients required catheterization.

Since there is nothing in our statistics to indicate that our procedure is of any value in promoting voiding after extensive vaginal plastic operations, we have returned to the use of an indwelling male catheter for the first week. Certainly with the interposition operation this is the logical procedure, as only 28 per cent of the patients voided spontaneously. There is little doubt that infection travels into the bladder via the indwelling catheter, but this is apparently of little significance since few of these patients have bladder symptoms following removal of the catheter. When it is removed at the end of a week the bladder has generally so regained its tone that spontaneous and complete micturition follows. If there is any indication of residual urine the patient should be catheterized until it has been proved that such a residue no longer exists.

The importance of avoiding overdistention of the bladder was well illustrated in one of our interposition cases. The patient began to void spontaneously postoperatively but voided frequently and in small amounts without relief. She was finally catheterized on the third day, and 700 cc. of urine was obtained. In the next twenty-four hours she was catheterized for great distress three times, and 800 cc., 700 cc. and 450 cc. of urine were obtained successively. On the fourth postoperative day her temperature rose to 103 F. and she had costovertebral tenderness on the right. On the fifth day an indwelling catheter was inserted, and the temperature became normal in twenty-four hours. This case also indicates that a routine order for catheterization every eight hours if the patient voids less than 100 cc. at one time is not entirely satisfactory. This patient voided as much as 200 cc. at a time but apparently only as an overflow. She should have been catheterized for bladder distress long before her bladder

became so distended, but the nurse, adhering literally to the 100 cc. rule, failed to pay proper attention to the patient's distress. With such severe bladder discomfort the nurse should have called the intern, who undoubtedly would have ordered catheterization earlier.

SUMMARY

A special technic to promote postoperative voiding consists of instilling into the bladder 1 ounce of 0.5 per cent aqueous solution of mercurochrome in the operating room. The results after pelvic laparotomies have been very gratifying, the incidence of catheterization having been reduced from 51 per cent in a control series to 6.5 per cent in a series of 500 cases in which this procedure was used. An instillation of a liter of fluid by rectum at the same time was found to be of no value in reducing the incidence of catheterization. Evidence has been presented to show that the patients in whom the instillation was used voided earlier and in greater amounts, thus more completely emptying the bladder than the patients in the control series. It has been shown that the shorter the anesthesia the greater the likelihood of spontaneous postoperative micturition. The patients receiving a basal anesthesia of avertin with amylene hydrate required catheterization in 8.2 per cent while those given straight gas, oxygen and ether required catheterization in only 3.7 per cent. Postoperative urinary tract infection, as judged by symptoms of cystitis on discharge and pyelitis, did not occur after any of the 500 laparotomies in which the procedure was carried out, with the exception of three cases. In each of these there was a definite history of urinary tract infection preoperatively. The procedure has been shown to be of no value in case of extensive plastic operation, in which an indwelling male catheter is considered the most satisfactory procedure.

ABSTRACT OF DISCUSSION

DR. GEORGE H. GARDNER, Chicago: An ideal method of managing the bladder after gynecologic operations should be equally effective after all types of operations, cause the patient a minimum of discomfort, safeguard the integrity of sutures that have been placed near the bladder, and finally not only eliminate acute complications of the upper urinary tract from postoperative problems but also obviate chronic conditions in the lower urinary tract as permanent sequelae of gynecologic surgery. The technic which Dr. Arthur H. Curtis described and which has been the routine in our service at Passavant Memorial Hospital for ten years is a close approach to the ideal. Our patients are subjected to intermittent catheterization; they do not have indwelling catheters. They are catheterized for distress, not after any specified number of hours, but for any marked discomfort which may be ascribable to a distended bladder. We endeavor to avoid overdistention and consider the accumulation of more than 350 cc. of urine as being potentially harmful. After a woman has been catheterized two or more times or has worn an indwelling catheter, her bladder is infected. Such an infection rarely attains significant proportions, if the physician and his staff are residual urine conscious. Consequently, after our patients start to void they are catheterized once or twice daily for residual urine until that residual is persistently less than 15 cc. in amount and is grossly clear. I prefer intermittent catheterization with routine check for residual urine, because this method is equally applicable to all patients and we realize that simplicity in hospital routine makes for more efficient care of patients. We do not favor retention catheters, either male or de Pezzer, because they give one a false sense of security; indwelling catheters do not always drain the bladder completely, as they tend to become displaced and plugged. After a retention catheter has been removed it is vital that the patient be checked in a routine way for residual urine.

DR. WILLIAM T. KENNEDY, New York: Nature has to overcome obstacles to restore the bladder to normal following pelvic or vaginal operations. First, some patients come for operation having been below par physically; they have very mild, low grade infections of the upper urinary tract, with some desquamation. This at operation suddenly becomes more active and for the first few postoperative days the sediment in the bladder is increased; this with the associated loss of muscle tone of the bladder permits the accumulation of a precipitate which on standing breaks down into the alkaline ammonia salts to irritate the base of the bladder. Only part of this precipitate passes out when the patient voids. Nature has two resources: one, to increase the flush from the kidneys; the other, to send bacteria in to clean up this mixture of mucus, desquamated cells, and so on. The colon bacilli are those elected. How they get in I do not know, but I doubt that it is through the urethra. Here is our opportunity to help nature. The first catheterization for residual urine is done and it is allowed to stand for a couple of hours for sedimentation. If sediment is present, the bladder is irrigated with boric acid solution and an ounce of 10 per cent solution of caroid or papain instilled into the bladder. This will materially aid in clearing up the base of the bladder. This is repeated daily for three or four times. Instillation of antiseptics at this time would only inhibit nature's bacterial processes. With the recent advent of neoprontosil, I feel that much could be accomplished in preventing this complication by giving the drug three or four days before operation. Second, the next obstacle to overcome is the diminished function of the kidneys. This is best activated by clysis or intravenous saline solution or dextrose, as well as all the fluids which can be tolerated by mouth. Drs. Woodruff and Te Linde found that the rectal instillation had little effect on the bladder. Most fluids are used by the body in counteracting dehydration. The return of the urine flow to normal may roughly be estimated by the excretion of 400, 800, 1,200 and 1,600 cc. on the first four successive days. Third, the next obstacle nature has to overcome is the loss of bladder muscle tone either when the bladder structures have been unmolested or considerably disturbed by operative procedures. Comparing the treated cases with the untreated controls for the time of first voiding and the amount voided, one is amazed that the treated bladder voids more urine than the untreated one and almost twice as soon. The kidneys were either more active or there was less residual urine, and I am forced to believe there was less residual urine. The authors have made definite progress in eliminating this worst offender (residual urine). In the care of the bladder after operation I use an indwelling male catheter for about a week, watch the urine carefully for sediment and, if it appears, irrigate the bladder and instil caroid or papain solution into it. After the catheter has been removed I catheterize the patient twice a day immediately after voiding until the residual urine is one-half ounce or less.

Greater Mortality Among Males.—About one quarter of the known pregnancies result in stillbirths. Great numbers of these aborted babies have been examined, and some surprising data obtained. In embryos aborted when they are about three months old, specialists can already distinguish sex, and in these early mortalities they have found that the males outnumber the females almost four to one. These, however, are but a small percentage of the total stillbirths. In those in the fourth month, aborted males are double those of females, in the fifth month 145 males to 100 females, in the next few months the proportion drops further, but just before birth there is a rise to almost 140 males aborted to every 100 females. All this leads to another conclusion: That before birth, certainly, males as a class are not only not stronger than females but, quite on the contrary, are weaker. If we look beyond birth we find, moreover, that at almost every stage of life, males drop out at a higher rate than females. It may very well be, then, that a canny Nature enters more males than females at the start of life's race in order to counterbalance the difference in mortality.—Scheinfeld, Amram: You and Heredity, New York, Frederick A. Stokes Company, 1939.

PRIMARY PERITONITIS IN INFANTS
AND CHILDREN

A MORE EFFECTIVE TREATMENT

WILLIAM E. LADD, M.D.

THOMAS W. BOTSFORD, M.D.

AND

EDWARD C. CURNEN, M.D.

BOSTON

Primary, idiopathic or metastatic peritonitis has always been associated with a very high mortality rate in infants and children. In recent years, with the use of sulfanilamide and antipneumococcus serum, we have markedly lowered the mortality rate in this disease and have revised our therapeutic approach. It is our purpose in this paper to present an effective treatment of the disease and the information gained from sixty-seven cases of primary peritonitis observed in the ten year period 1929-1939 at the Children's Hospital.

ETIOLOGY

The offending organism in primary peritonitis is usually the pneumococcus or the hemolytic streptococcus. Three patients with primary peritonitis, not included in this series, were encountered in whom no organisms were demonstrable by direct smear or culture of the peritoneal exudate. The streptococcus was found more than twice as frequently as the pneumococcus, since there were forty-seven cases attributable to the former and twenty cases to the latter.

The pathways by which the organism may enter the peritoneal cavity have received detailed consideration in previous reports.¹ The possible modes of entry are by way of (1) the blood stream, (2) the vagina and fallopian tubes in females, (3) the gastrointestinal tract and (4) the transdiaphragmatic lymphatics.

In the present series blood cultures were made on twelve patients with pneumococcic peritonitis, and ten of these were positive. Similar cultures were made on eighteen patients with streptococcic peritonitis, and four were positive. Cultures of material from the vagina were taken of three patients with pneumococcic peritonitis, and one yielded the same type of pneumococcus as that isolated from the peritoneal cavity. Vaginal cultures were taken of six patients in the streptococcus group, and three were positive for hemolytic streptococci. Cultures of material taken from the throat of five patients with pneumococcic peritonitis failed to reveal the offending organism, although in each other types of pneumococci were isolated. In the streptococcus group, four throat cultures were made and two of these were positive for hemolytic streptococci.

Of the forty-one patients who died, twenty came to autopsy, including eight females. In no instance was there evidence of an ascending infection along the genital tract.² In the absence of more convincing evidence concerning the other possible routes, we feel that the probable mode of entry is by way of the blood stream.

The types of pneumococci isolated in peritonitis have not been noted in the majority of publications on the subject, but those reported show a preponderance of the type I pneumococcus.³ In the present series of cases there were five of type I, four of type VI, two of type V and one each of types IV, VIII, X, XI, XVIII and XXII. No conclusions can be drawn from the available material as to the relation of the type of pneumococcus to the severity of the peritonitis.

AGE AND SEX

The disease is much more common in the first four years of life, as shown in the accompanying chart. Streptococcic peritonitis has its highest incidence during infancy, whereas pneumococcic peritonitis predominates between the ages of 2 and 7 years. The latter observation is in accord with the observations of McCartney and Fraser.¹

There were no appreciable differences in the sexes in the total group or when they were divided into their etiologic groups (table 1). However, it is to be noted that six of the male patients in the pneumococcic group had nephrosis whereas only two females of the same group had nephrosis. Excluding the patients with

Incidence of primary peritonitis according to age.

nephrosis, there would be a definite preponderance of females in the pneumococcic group, an observation that has been emphasized repeatedly.⁴

CLINICAL FEATURES AND DIAGNOSIS

Primary peritonitis was preceded by an infection of the upper respiratory tract, mild or severe, in more than one half of the cases. In several cases there had been a previous otitis media or a cervical adenitis. The onset was acute and was associated with fever, abdominal pain, nausea and vomiting. The abdominal pain may be difficult to localize in infants and children, but in a large number of instances it appeared to be periumbilical. Diarrhea was a common symptom and at times was profuse. The diarrhea, if present, usually appeared in the first thirty-six hours of the disease. Some of the common symptoms and their incidence are listed in table 2.

On physical examination, patients with primary peritonitis appear severely ill and are frequently prostrated. Signs of infection of the upper respiratory tract may be present. The temperature is elevated between 103 and 105 F. and the pulse is correspondingly rapid. The abdomen is diffusely tender throughout and the general-

ized involuntary spasm may be boardlike. In infants up to 2 years of age, however, the abdomen may be "doughy" rather than spastic to palpation. Abdominal distention of varying degree may be present. Rectal examination reveals diffuse tenderness, although occasionally a pelvic abscess is detected. The remainder of the physical examination is remarkable in that it reveals nothing severe enough to account for the "toxic" picture. The leukocyte count varies between 20,000 and 50,000, with more than 80 per cent polymorphonuclear leukocytes. Urinalysis usually reveals the presence of acetone.

It is impossible to differentiate between streptococcic and pneumococcic peritonitis clinically, but we feel that primary peritonitis can usually be distinguished from

secondary peritonitis. In the present series the correct diagnosis of primary peritonitis was made in 64 per cent of the cases on entry. We do not agree with the statement of Leopold and Kaufman⁴ that "a definite clinical diagnosis of peritonitis cannot be made without operation or abdominal tap."

The condition most likely to be confused in diagnosis is acute perforated appendicitis with generalized peritonitis. However, in primary peritonitis there often has been a preceding infection of the upper respiratory tract. The age is important, as appendicitis is infrequent in the first two years of life. The patient is sicker from the onset, which may be initiated by a chill, and diarrhea is more likely to be associated with primary peritonitis than with appendicitis. Furthermore, the abdominal signs are more generalized and the fever is higher. The leukocyte count is usually higher than in peritonitis of appendical origin. It is obvious that in some instances the diagnosis between primary and secondary peritonitis will not be clear until the character of the peritoneal exudate is studied.

TREATMENT

As soon as the clinical diagnosis of primary peritonitis is made, the organism responsible must be recovered in the quickest possible manner in order that specific therapy can be instituted. Our method of choice for recovering the organism is operative. The patient is given parenteral fluids if indicated and then taken to the operating room, where under local or cyclopropane anesthesia a 1 inch muscle-splitting incision is made in the right lower quadrant. The peritoneum is merely nicked, and sufficient exudate for smear and culture is obtained by swab or gentle aspiration through a rubber catheter. A Penrose drain is inserted and the wound is closed to the drain with two or three sutures. It is important to point out that no exploration is performed and that the purpose of the procedure is to recover peritoneal exudate and incidentally to insert a drain. The advantages of this method for recovering the organism are that: 1. It is a minor operation and can be performed under local anesthesia in infants and very

sick patients. 2. The results are never equivocal. 3. Drainage is established, which we feel is of considerable value, although we realize that it is impossible to drain the entire peritoneal cavity. 4. The procedure is not shocking and does not upset the patient. 5. If the peritonitis is due to appendicitis, the incision is easily enlarged for an appendectomy. Abdominal paracentesis has been advocated⁵ as the procedure of choice for recovering organisms from the peritoneal cavity. We do not recommend it because, (1) if the results are negative, primary peritonitis has not been ruled out; (2) if the peritonitis is of appendical origin, appendectomy cannot be performed, and (3) the needle may enter a loop of bowel, which may do no harm but is undesirable.

The gross appearance of the peritoneal exudate is important. In pneumococcic peritonitis the exudate is odorless, fibrinous and soapy, while in streptococcic peritonitis it is odorless and thin and contains small flecks of fibrin. As soon as the exudate is obtained it is stained by Gram's method and cultured on blood plates, beef broth and human ascitic fluid. If the pneumococcus is present it will usually grow out in the human ascitic fluid within three hours and then can be typed. The stained smear gives an immediate clue as to the identity of the organism. It is apparent from the foregoing that the specific therapy can be instituted within several hours after the patient enters the hospital. The administration of the specific therapy will be discussed later.

The after-care of the patient is very important. The patient is placed in a high Fowler's position and given morphine sulfate subcutaneously every four hours by the clock for the first thirty-six to forty-eight hours. Hot flaxseed poultices are applied to the abdomen every three hours. The water balance is maintained by intravenous injections of 10 per cent dextrose solution and hypodermoclyses of physiologic solution of sodium chloride. Blood transfusions are liberally employed for anemia or hypoproteinemia. If the patient does not vomit and there is no distention, water and dilute fruit juices are given by mouth several hours after opera-

tion. Fluid by mouth is increased gradually and a semisolid diet is reached by the third or fourth postoperative day. If there is vomiting or distention, constant gastric siphonage is employed. We have found the high concentration of oxygen as advocated by Fine and his associates⁶ to be a valuable addition to the treatment of distention in patients with primary peritonitis. The wound is dressed frequently enough to keep it dry. The sutures are removed from the wound on the seventh postoperative day, and the abdominal

drain is removed between the seventh and tenth post-operative days. It is of interest that only two patients in this series required an enterostomy for intestinal obstruction following primary peritonitis.

SPECIFIC THERAPY IN STREPTOCOCCIC PERITONITIS

The dosage and method of administering sulfanilamide in use at the Children's Hospital have been reported previously by Carey.⁷ In primary peritonitis, treatment with sulfanilamide may be instituted as soon as the patient has returned to the ward from the operating room, even before the results of the peritoneal culture are known. If a pneumococcus is isolated, sulfapyridine may be substituted and continued in conjunction with specific serum therapy. The initial dose of sulfanilamide may be given by hypodermoclysis of an 0.8 per cent solution in physiologic solution of sodium

to have symptoms of acute appendicitis and an exploration was performed immediately. Operation revealed the true nature of the disease and pathologic examination of the appendix showed only periappendicitis. In all cases the bacteriologic diagnosis was established by cultures of the peritoneal cavity obtained at operation. Early operation was performed in all but two of the cases (cases 2 and 3). In case 3 the operation was deferred four days, and not until then was specific treatment started. Recovery followed a prolonged and stormy course. In case 2, in which the illness terminated fatally, incision of the abdomen was deferred for about eighteen hours. None of the patients with streptococcic infection who recovered had positive blood cultures, although all of them were critically ill.

The first two patients (1 and 2) who were treated with sulfanilamide received very small amounts of the drug and died. The other five patients received doses

chloride and maintained by oral administration of crushed tablets as soon as the patient is able to tolerate fluids by mouth. During the first two or three days of treatment, doses of from 0.1 to 0.15 Gm. per pound of body weight in twenty-four hours will usually be sufficient to establish an optimal blood level of from 10 to 20 mg. per hundred cubic centimeters as estimated according to the method of Marshall.⁸ The dose may be reduced by one half when definite clinical improvement is in evidence and discontinued about one week later, according to the indications in the individual case. In several of the cases reported here, administration was discontinued earlier than would seem advisable.

Seven patients with primary peritonitis due to the hemolytic streptococcus received sulfanilamide (table 3). In six of the cases the diagnosis of primary peritonitis was made at entry. One patient (case 6) was thought

of from 0.06 to 0.1 Gm. per pound for periods which varied from one to twelve days. In most of the cases the blood levels were not recorded, and the drug was administered and discontinued arbitrarily according to the clinical appearance. Satisfactory concentrations of sulfanilamide were obtained in the blood of two patients who responded to treatment by a prompt drop in temperature and early clinical improvement. Patient 6, who made an uneventful recovery, received a dose of 0.06 Gm. per pound for only twenty-four hours, at which time the drug was discontinued because of marked nausea. While under treatment, all the patients appeared cyanotic and in all moderate anemia developed which was treated by blood transfusions.

SPECIFIC THERAPY IN PNEUMOCOCCIC PERITONITIS

Before treatment with specific antipneumococcus serum, precautions are taken in each case to determine the presence or absence of sensitivity. This includes a careful inquiry into the past history for previous injections of serum or manifestations of allergy and the usual intradermal and ophthalmic tests with a 1:10 dilution

of the animal serum to be used. During the testing and administration of serum, epinephrine solution should always be available for immediate use. Serum treatment is deferred postoperatively until the patient's circulation and general condition are sufficiently restored to minimize the danger of precipitatory collapse.

Serum was given exclusively by the intravenous route. The schedule of administration, gradually formulated, consisted of an initial injection of 1 cc. followed at frequent intervals of at least two hours by larger injections of from 3 to 10 cc. To minimize reactions, slowness of injection was deemed of great importance. This was facilitated by diluting each dose of serum in from 5 to 10 volumes of physiologic solution of sodium chloride. Small quantities were delivered from a standard syringe; large amounts were given as an infusion or injected through the rubber tubing of a constant

showed no growth. The blood stream of one bacteremic patient (5) was temporarily sterilized by the administration of specific antibody but reinvasion occurred and, despite continued treatment, persisted until death. Another patient (8) whose blood culture before operation was positive had a remission of symptoms and negative blood cultures postoperatively, even before specific antipneumococcic treatment was started.

Surgical incision and drainage of the abdomen was performed in seven of the eight cases. In six cases this was carried out at the earliest possible opportunity; that is, on the day of onset or admission to the hospital. Early conservatism in the policy of treating one patient (3) resulted in a considerable, although fortunately not a fatal, delay in operating and establishing the bacteriologic diagnosis. Administration of serum was started in this case prior to surgical drainage on the evidence

* The rabbit serum used in the last four patients from Lederle's Laboratories.

intravenous drip. When the anticubital veins were inaccessible, 24 gage needles were used and the serum was injected into small veins of the extremities or scalp.

Eight patients with proved pneumococcic peritonitis were treated more or less according to the method advocated (table 4). In every case a clinical diagnosis of primary peritonitis was promptly made from the history and physical examinations, and the bacteriologic diagnosis was established on the basis of cultures obtained from the peritoneal cavity. In six of the eight cases early operation on the day of entry to the hospital facilitated identification of the responsible pneumococcus within a few hours. In two cases (3 and 5) the invading organism was not sought immediately in the peritoneal cavity and was first detected in the blood cultures.

Bacteremia was present prior to specific serum therapy in six of the eight cases. In each instance the organism obtained from the blood stream was identical with that from the peritoneal cavity. In five of the cases all blood cultures taken subsequent to serum treatment

of a positive blood culture. At operation the appendix was removed from two patients (1 and 3) because injection and fibrin deposits on the serosal surface suggested the possibility of primary appendical involvement and the patient's condition warranted this manipulation. Subsequent pathologic examination, however, revealed only periappendicitis. Abdominal paracentesis was substituted for surgical drainage in case 5, nephrosis, in which the illness terminated fatally.

The amount of antibody required appeared to vary with individual cases, and the number reported here are too few to warrant definite conclusions. As the nature of the infection is severe, highly fatal and usually accompanied by bacteremia, serum was administered in large doses during the first twenty-four to forty-eight hours and continued until the blood stream was sterile and definite clinical improvement was in evidence. Immunologic studies were carried out in some of the more recent cases, but the data available do not at present offer a more accurate basis of estimating the antibody requirement. Reactions to serum occurred in

three cases but in no instance proved alarming. Serum sickness appeared during convalescence in two cases.

Because the bacteriostatic action of sulfanilamide against the pneumococcus has been demonstrated in vitro and applied successfully in the treatment of pneumococcic meningitis,⁹ this drug was included in the therapy of three patients (5, 6 and 7), but in only one (case 6) was a satisfactory concentration of this drug in the blood achieved and maintained. Recent reports¹⁰ on the efficacy of sulfapyridine in the treatment of pneumococcic peritonitis encouraged the administration of this drug in case 8. Clinical improvement, however, seemed to occur and the patient became non-bacteremic before the administration of sulfapyridine or serum, so that no definite conclusions can be derived in this case as to the benefit of either.

Complications attributable to the offending pneumococcus occurred in five cases, in three of which bacteremia was proved. In the four cases of type I infection pneumonia developed as a secondary disorder and was followed in two cases by empyema requiring surgical drainage (cases 1 and 3). In one case an abscess of the abdominal wall developed together with a fecal fistula, which healed slowly without surgical intervention. In case 4 a pelvic abscess developed and resolved gradually. In the case of type IV infection, the complications were incident to a fatal termination. The patient was a boy with lipoid nephrosis, whose symptoms were initiated by a chill and a sudden rise in fever while under treatment for nephrosis in this hospital. Type IV pneumococci were identified in a blood culture fourteen hours later. An abdominal paracentesis done at this time yielded the same organism. No operation was performed. Serum was administered in daily doses of 180,000, 80,000, 40,000, 40,000 and 40,000 units, starting on the second day, or about fifteen hours after onset. On the first day of treatment the

of cases is divided into those in which specific therapy was and was not given, there is a striking difference in the mortality rates (table 6). It is at once evident that the total rate has been lowered more than 50 per cent. In the pneumococcic group with early operation and specific therapy there is only 12.5 per cent mortality, in contrast to 83.3 per cent in those without the advocated therapy. On the other hand the streptococcic group

TABLE 6.—Mortality Rates in Pneumococcic and Streptococcic Peritonitis With and Without Specific Therapy

Children's Hospital, Primary Peritonitis 1929-1939	Without Specific Therapy			With Specific Therapy		
	Total Cases	Deaths	Mortality, per Cent	Total Cases	Deaths	Mortality, per Cent
All primary cases...	52	38	73.0	15	3	20.0
Pneumococci.....	12	10	83.3	8	1	12.5
Streptococci.....	40	28	72.0	7	2	28.5

presents a less striking but significant drop in the mortality of 72 per cent to 28.5 per cent in the corresponding groups. As pointed out previously in this paper, the one patient with pneumococcic peritonitis and the two with streptococcic peritonitis who were given specific therapy and died were not given adequate specific treatment.

COMMENT

In the present clinical study of primary peritonitis, the benefits of early operation and adequate specific therapy have been reflected by a significant reduction in the mortality. The details of treatment remain somewhat elastic and, as pointed out elsewhere, not all of the patients were treated according to our present concept of the most effective procedure. The virulence of the organism and the resistance of the patient are two factors in primary peritonitis which always play an important role, which is difficult to evaluate in discussing the results of any type of treatment. Several cases of pneumococcic peritonitis successfully treated with sulfapyridine have been reported¹⁰ recently. This may prove a valuable adjunct to the serum therapy of the disease.

The present program of treatment of primary peritonitis that we advocate following is as follows:

1. Early incision and drainage of the peritoneal cavity with minimal manipulation.
2. Identification as rapidly as possible of the offending organism obtained from the peritoneal cavity.
3. Immediate postoperative institution of sulfanilamide therapy by hypodermoclysis, continued by oral administration when fluids can be taken by mouth.
4. If a pneumococcus is obtained, substitution of sulfapyridine for sulfanilamide therapy and intravenous administration of type specific antipneumococcus serum.
5. (a) Use of high concentration oxygen and gastric siphonage to relieve abdominal distention; (b) maintenance of adequate fluid intake by parenteral and enteral routes; (c) repeated small blood transfusions to combat anemia and hypoproteinemia.

CONCLUSION

The high mortality rate in primary peritonitis can be strikingly reduced by early operation for recovery of the offending organism and drainage followed by adequate treatment with sulfanilamide in the streptococcic group and with type specific serum in the pneumococcic group.

blood cultures were negative and agglutinins were demonstrated in the patient's serum. Improvement in the patient's condition lasted for four days and then bacteremia recurred; the patient's condition declined until the eighth day, when he died.

MORTALITY

A characteristic feature of primary peritonitis is that it has been universally accepted that it has a high mortality rate (table 5). However, when the present series

FACTORS IN RECURRENCE OF
RENAL CALCULI

CHARLES C. HIGGINS, M.D.

CLEVELAND

The recurrent formation of renal calculi following the surgical removal of a stone from the kidney constitutes a major problem in the management of patients with renal lithiasis. That formation of secondary calculi will frequently occur unless adequate preventive measures are instituted seems plausible when it is obvious that, in the majority of instances, the underlying factors associated with the production of the primary calculus are not corrected or eradicated by the surgical procedure.

From experimental and clinical observation, it appears evident that no one etiologic agent is entirely responsible for the formation of all kidney stones. This emphasizes the necessity for an intensive preoperative investigation to ascertain the causative factors in each individual case. This facilitates correction of these factors at the time of surgical treatment or during the postoperative regimen. Certainly the operative procedure per se constitutes but one phase in the management of this group of patients, and to neglect an exacting preoperative investigation and adequate postoperative supervision will be attended by an unwarranted high incidence of recurrences. It is also evident that, while an investigation of the etiologic factors is essential during the preoperative period, additional factors known to be associated with the formation of calculi may be introduced or be directly attributed to surgical intervention, namely, trauma, infection and conditions conducive to the production of stasis.

Recurrent renal calculi may be of either one of the following two types:

1. True recurrence or the formation of a calculus after complete removal of the original stone.
2. False recurrence, or a persistence of stones or fragments of a calculus overlooked at the time of operation.

A knowledge of the true incidence of these recurrences is influenced by the frequency with which postoperative roentgenograms are secured. Misinterpretation of end results cannot be avoided unless roentgen study is made as a routine procedure after the operation. A small calculus may be overlooked at the time of operation, especially if multiple stones are being removed. Unless a roentgenogram is secured before the patient is dismissed from the hospital a recurrence, either asymptomatic in type or productive of renal colic, and which is noted by roentgen studies months later, may be misconstrued as a true recurrence or a stone that formed de novo, whereas it is really a false recurrence. When multiple calculi are being removed, I believe that a roentgenogram of the exposed kidney should be secured at the time of operation in order to avoid overlooking a small stone.

It is evident from the contributions of several authors that a progressive decrease in the incidence of recurrent renal calculi is taking place. In 1915 Cabot and Crabtree,¹ in reviewing the results secured in the treatment of renal calculi at the Massachusetts General Hospital,

reported that "recurrence" took place in 56 per cent of patients treated by nephrotomy and in 51 per cent of those treated by pyelotomy.

Barney² in 1922 again studied a series of cases from the Massachusetts General Hospital and stated that the incidence of recurrence was 32 per cent following the removal of a calculus from the kidney; however, it is interesting to note that postoperative roentgenograms revealed that stones were still present in the kidney in nine of twenty cases, or 45 per cent.

Braasch and Foulds³ in 1924 stated that calculi recurred in 10.79 per cent of the patients who were operated on at the Mayo Clinic. Herbst⁴ has noted the incidence of recurrence as 15 per cent, while Hunner⁵ in 1927 gave the incidence as 9.5 per cent following operations for renal stones and as 4.4 per cent following operations for ureteral calculi.

Oppenheimer⁶ in 1937 cited true recurrences following pyelolithotomy, pyelonephrolithotomy and nephrotomy in 14.9 per cent, 32.0 per cent and 29.4 per cent, respectively, of his cases.

Twinn⁷ in 1937 reviewed 314 operations for stone performed at the New York Hospital and stated that there were 28 per cent recurrences following nephrotomy and 20.9 per cent following pyelotomy. During the preceding year and a half, however, he stated that recurrences had been reduced to 5.3 per cent. At the Cleveland Clinic the incidence of recurrence prior to 1933 was 16.4 per cent. Between the years 1933 and 1939 this has been reduced to 4.9 per cent by adding the high vitamin A acid ash or alkaline ash diet to the other postoperative measures, thereby controlling the pH of the urine.

INFECTION

The relationship between infection and the formation of primary or recurrent calculi has been stressed for a long time. Brongersma's⁸ statistics illustrate the relationship between infection and recurrent renal lithiasis. In the absence of infection the incidence of recurrence was between 3 and 6 per cent, but it was approximately 27 per cent when the infection was slight and 50 per cent when severe.

Rovsing⁹ found that 68.18 per cent of all recurrences occurred when renal infection, either primary or secondary, was due to urea-splitting organisms. However, in 15.91 per cent of his cases the recurrences developed in the presence of sterile urine. Ten examples of renal stone due to the staphylococcus were reported by Boshamer¹⁰ in 1932. The formation of these calculi was probably due to the ability of certain members of this group to split the urea in the urine with the resultant formation of ammonia, a reaction favorable to the precipitation of the alkaline salts in the urine. In 1935 Runeberg¹¹ stressed the importance of anaerobic organisms in the genesis of calculi.

From the Cleveland Clinic.

Read before the Section on Urology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 19, 1939.

1. Cabot, Hugh, and Crabtree, E. G.: Frequency of Recurrence of Stone in the Kidney After Operation, Surg., Gynec. & Obst. 21: 223-225, 1915.

A study of a series of 200 patients with recurrent renal calculi made at the Cleveland Clinic showed a coexisting renal infection in 81.5 per cent of the cases (figs. 1, 2 and 3), while the urine was sterile in 18.5 per cent (fig. 4). It was noted that when the stones were large an infection was usually present, while the urine was more frequently sterile in the presence of smaller calculi.

Determination of the chemical constituents of stones formed in the presence of sterile urine showed them usually to be composed of uric acid, cystine or oxalates, while the recurrent stones associated with renal infection were generally composed of phosphates, carbonates or mixtures of these salts with occasional traces of oxalates.

In considering the relationship of infection to recurrence, two types of infection must be considered. If the organisms possess the power of splitting urea, such as *Bacillus proteus*, there is a greater tendency for a recurrent calculus to develop than when the infection is due to *Bacillus coli*, an acid-forming organism which does not possess this power. This requires further elucidation, however, since the reports of Brown and Earlam¹² in 1933. These authors stated that 18 per cent of the bacilli which infect the urinary tract possess the power of splitting urea and that 40 per cent of *Staphylococcus albus* have similar properties. These organisms split the urea in the urine with the resultant formation of ammonia and carbon dioxide. This shifts the p_H of the urine to the alkaline side, enhancing the precipitation of the alkaline salts, i. e. phosphates and carbonates.

Fig. 1.—Recurrent renal calculi associated with proteus infection.

In the present series of cases, 9 per cent of the bacilli and 18 per cent of the staphylococci possessed this power. It was also noted that infection of the kidneys was much more frequent in the patients with bilateral recurrent renal calculi than in those with unilateral stones. The predominant organism cultured was *Staphylococcus albus*. It was found most frequently

in pure culture and usually was present in the mixed infections. *Bacillus proteus* in pure culture was the second chief offender, although other bacilli and streptococci in mixed cultures were often observed.

As the selection of medication employed to eradicate the renal infection may be influenced by knowledge as to whether the organisms split urea—and, in fact, certain drugs such as ammonium chloride may be contra-

Fig. 2.—Recurrent renal calculi associated with colon bacillus infection, the organism having the power of splitting urea.

indicated in the presence of a proteus infection—it should be a routine part of one's bacteriologic study to determine whether the offending organisms have the power of splitting urea. Similarly, in addition to a culture, a stained smear of the urinary sediment should be made in each case. While it appears true that infection plays a major role in the production of recurrent renal calculi, in view of the clinical observation that many recurrences develop in the presence of sterile urine, further search for etiologic factors is essential.

FOCAL INFECTION

In 1921 Rosenow and Meisser¹³ presented their experimental data which indicated the role of focal infection in the formation of renal calculi. They inoculated the pulps of the teeth of dogs with streptococci isolated from the urine of patients with renal lithiasis. Following this, calculi developed in the dogs and streptococci were again isolated from the urine.

In reviewing the present series of 200 recurrent renal calculi, definite foci of infection could be demonstrated in many instances, but there was no apparent relationship between the organisms cultured from these sites and those isolated from the urine. In view of the work of Rosenow and Meisser, however, I believe that foci present in the teeth, tonsils, cervix and prostate should be eliminated.

STASIS

Urosthesis in many instances seems definitely to be associated with the formation of recurrent renal calculi, and its presence is conducive to shifting the p_H of the

RECURRENCE OF CALCULI—HIGGINS

1462

urine to the alkaline side. Hunner¹⁴ in 1924 stressed the importance of ureteral stricture in the formation of renal calculi.

In this series the intravenous urogram revealed evidence of stasis in 72 per cent of the cases. Either the calculus was producing varying degrees of obstruction at the ureteropelvic junction or obstruction was demonstrated in a calix containing the stone. It is difficult from the analysis of this group of cases to form an opinion as to whether stasis preceded the formation of the recurrent calculus or was produced subsequent to the formation of the calculus. In twenty-one instances a stone formed in the kidney following the surgical removal of a stone from the ureter on the same side (figs. 5 and 6).

Intravenous urograms in this group elicited definite evidence of ureteral obstruction at the site at which the calculus was removed in twelve instances. This serves to emphasize the value of employing intravenous urographic studies following the removal of a calculus from the ureter. These recurrences could probably have been prevented by dilation of the ureter and adequate care in the postoperative regimen.

VITAMIN A DEFICIENCY

Experimental and clinical observations demonstrating the relationship between a deficiency of vitamin A in the diet and the formation of renal calculi have been discussed previously.¹⁵ Some authors have stated that there is no evidence of deficiency of vitamin A among the people of this country. This presumption is based

Fig. 3.—Recurrent renal lithiasis associated with *Staphylococcus albus* infection, the organism having the power of splitting urea.

on impressions gained only from dietary histories elicited from the patients and may lead to erroneous deductions. The history alone does not provide sufficient evidence to state whether a person is receiving or utilizing adequate amounts of vitamin A, and biophotometric studies have shown how unreliable such information may be.

14. Hunner, G. L.: Ureteral Stricture: Report of Unusual Case Illustrating Influence on Formation of Urinary Calculi, *J. A. M. A.* 82: 509-516 (Feb. 16) 1924.

In previous communications I¹⁶ have noted that from 68 to 72 per cent of patients with renal calculi had a positive reaction to the biophotometer test, and in this study of patients with recurrent renal calculi 48 per cent had various degrees of vitamin A deficiency as shown by this method.

Dr. W. J. Ezickson¹⁷ in a personal communication stated: "There were twenty-five patients in our first

Fig. 4.—Recurrent renal calculus. Urine sterile.

series who have or have had renal calculi who were studied for vitamin A deficiency by means of the dark adaptation test. Twenty-four of these showed a pathological dark adaptation and only one was normal.

Jeghers¹⁸ stated: "More important, however, was the demonstration of the frequency of clinically detectable vitamin A deficiency in a group of 162 students examined. Of this group, 35 per cent had low photometric readings and 12 per cent had clinical manifestations of vitamin A deficiency." Youmans, in discussing Jeghers' paper, stated that when using a similar photometric test he found subnormal dark adaptation in one half of fifty clinic patients, the diets of many of whom were thought to be inadequate. In eleven of fifty-four supposedly normal subjects whose diets appeared to be well balanced a similar observation was made.

From these reports and those of Jeans¹⁹ and others it appears evident that varying degrees of vitamin A deficiency are more prevalent in this country than we have been led to believe. Vermooten²⁰ stated that calculi do not form in the South African Negro, as illustrated by a study of 1,091,000 Negro patients. According to his report the South African Negro lives

on a simple, stable diet which is rich in vitamin A, high in acid-ash base and extremely low in calcium.

I believe therefore that a biophotometer test to determine the absence or presence of vitamin A deficiency should be a part of the examination of every patient with calculous disease (fig. 7). Furthermore, my associates and I prescribe vitamin A as a routine in the postoperative course for two reasons: first, to correct vitamin A deficiency if it is present and, second, for its effect on the epithelial structures.

HYPERPARATHYROIDISM

Albright and Bloomberg,²¹ Barney and Mintz²² and others have stressed the relationship between hyperparathyroidism and renal lithiasis. Barney and Mintz in 1934 reported a series of eighteen cases in which a diagnosis of hyperparathyroidism had been made and verified by surgical intervention. In eleven (61.1 per cent) calculi were present in the urinary tract. The youngest patient was 13 years of age and the oldest was 62. Involvement of the bones to varying degrees was present in twelve cases, while in six others urinary calculi and changes in the bones were found to coexist. The renal calculi were bilateral in four (36 per cent) of the eleven cases. Barney and Mintz conclude that hyperparathyroidism is responsible for from 4 to 5 per cent of the cases of renal calculi. In almost 70 per cent of cases of hyperparathyroidism stones may be present, while in approximately 38 per cent the patients have

Fig. 5.—Stricture of right ureter following ureterolithotomy. Note stasis demonstrable by intravenous urogram.

changes in the bones and urinary tract. Barney and Mintz state and Albright and Bloomberg concur that hyperparathyroidism is so frequently a cause of renal lithiasis that in every patient with this condition it must be determined whether or not it is present. Therefore a careful study of the calcium and phosphorus content of the blood should be made in all patients with renal stones.

Griffin, Osterberg and Braasch,²³ in reviewing cases of urinary lithiasis at the Mayo Clinic, state that hyperparathyroidism was found to be an etiologic factor in less than 0.2 per cent of their cases. At the Cleveland Clinic, hyperparathyroidism has been associated with renal lithiasis in about 0.1 per cent of the cases. In one case in this series the presence of hyperparathyroidism was overlooked when the primary calculus was

Fig. 6.—Formation of renal calculus on the same side two years later.

removed. When the patient returned with a recurrent renal calculus a diagnosis of hyperparathyroidism was established and verified by blood studies. A tumor of the parathyroid glands was removed at the time of operation. Further recurrences have not developed.

Gilmour and Martin²⁴ have emphasized the relationship between the condition of the parathyroid glands and renal disease. Fowweather and Pyrah²⁵ in 1938 also studied the relationship between hyperparathyroidism and renal lithiasis. They noted the absence of any marked preponderance of high levels of blood calcium among cases of recurrent calculi as compared with those without recurrence. They state: "Hence the raised blood calcium which may be found in association with renal calculi is in general the result of renal damage, and the previous suggestions that it is not evidence of a primary hyperparathyroidism, which is the cause of the formation of calculi, is confirmed."

They state further that in the early stages of renal disease the response of the parathyroid glands to this stimulus may result, in a certain proportion of cases and for a certain length of time, in an enhanced activity of these glands, which is rather more than sufficient to counteract the tendency arising from renal disease, so that a raised blood calcium and to a less extent a reduced blood phosphorus make their appearance. As the renal disease progresses, the tendency toward a low

blood calcium and a high blood phosphorus appears to increase to a point beyond which it is impossible for the parathyroids to neutralize it, and thus the blood changes of advanced renal disease are evident. Thus careful selection must be made of patients in whom exploratory operation on the parathyroid glands is advised. It is true, however, that the possibility of hyperparathyroidism must be considered in all patients with renal lithiasis, and no preoperative investigation is complete without due consideration of this disease.

METABOLIC FACTORS

Cystinuria.—This is a familial disease which results from derangement of the intermediate protein metabolism of the body. In normal persons cystine is oxidized completely and the sulfur is excreted as a sulfate. It is stated that calculi develop in about 2.5 per cent of patients suffering from cystinuria (fig. 8). However, Seeger and Kearns²⁶ in 1925 collected 181 cases of

Fig. 7.—Biophotometric reading on a patient with recurrent renal calculi. Note the return to normal when adequate amounts of vitamin A were administered.

cystinuria, 124 of which were complicated by stone formation. Cystine may be found in the urine partly in solution and partly as a crystalline deposit. A diagnosis of cystinuria is made in the majority of cases by a microscopic examination of the urinary sediment. Treatment consists of increasing the solubility of the cystine in the urine by the administration of alkalis and by restriction of the protein intake. Maintenance of an alkaline reaction of the urine diminishes definitely the possibility of the formation of a calculus.

Gout.—Gout is another metabolic disease in which excessive amounts of crystalloids appear in the urine, microscopic examination of the sediment revealing the presence of uric acid crystals and urates. Not only may calculi composed of uric acid be produced, but the patient may experience attacks of colic as showers of uric acid crystals are passed. Other clinical manifestations of gout need not be present for uric acid calculi to form. Normally, in man, from 0.3 to 1.2 Gm. of uric acid is excreted daily. The amount excreted is

influenced by the diet of the individual. Postoperatively, a low purine diet in conjunction with the high vitamin A alkaline ash diet assists in minimizing the incidence of recurrent formation of this type of calculus.

Oxaluria.—Oxaluria has been stated by Neville²⁷ to be associated with a deficiency of vitamin B. Oxalic acid, which has both an exogenous and an endogenous source, is excreted in the urine in amounts of approximately 15 to 20 mg. daily. Experiments have indicated that, if an animal is maintained on a diet containing a fixed amount of calcium oxalate, the amount of the urinary oxalate can be increased by the administration of acids and decreased by alkalis. If the calculus is found to be composed of oxalates, the foods having a high oxalic acid content should be restricted in the postoperative regimen.

Xanthine.—Urinary calculi composed of xanthine are of rare occurrence. Kretschmer²⁸ in 1937 collected a series of fifteen cases and added one of his own. Mathews²⁹ states that the most important purine found in the human urine is uric acid, but there are present also from 30 to 50 mg. of purine bases—xanthine, hypoxanthine, guanine and adenine. He estimates that from 16 to 60 mg. of purine bases are eliminated in the urine daily as the purines are the end products of the metabolism of the nucleins. Postoperatively, foods with a high purine content should be restricted if the calculus is composed of xanthine.

Phosphaturia.—The type of phosphaturia present must be determined. Temporary phosphaturia may be caused by eating foods containing an excess of alkaline ash. Permanent, infected phosphaturia is associated with the presence of an organism that has the power of splitting urea. In this type the urea is transformed into ammonium carbonate, the ammonia then combining with the magnesium and phosphoric acid to form triple phosphate, while the carbonate combines with the calcium, forming calcium carbonate. Permanent, non-infected phosphaturia is stated to be due to alteration in function of the gastrointestinal tract.

Snapper³⁰ believes that all factors which tend to stabilize the labile colloids must help prevent the formation of stones. The presence of salicylates, mandelates, hippurates and other organic salts in the urine may, by increasing the stability of the urinary colloids, exercise a prophylactic influence against the formation of stones. He states:

Factors which may have a preventive or even a curative effect on the formation of renal calculi are:

1. Administration of foods with an acid-ash which increases the acidity of the urine and the solubility of the calcium salts.
2. Artificial acidosis by ingestion of ammonium chloride, ammonium nitrate, or other compounds.
3. Large supply of vitamin A.

Residues of kidney stones and urinary gravel may be prevented by the use of these measures. It is also evident that the presence of hippurates, salicylates, mandelates and other organic salts in the urine must be of great importance in the prevention of renal stones.

TRAUMA

A review of the literature indicates that recurrences following nephrolithotomy and nephropelviolithotomy are more frequent than when pelviolithotomy is

employed. In nine cases in this series a blood clot was found to be the nucleus for a recurrent stone. Braasch and Foulds³ in 1924 estimated a recurrence of 10.79 per cent, a recurrence of 11.85 per cent following pyelotomy and 24.03 per cent following nephrolithotomy. Certainly a minimum of trauma should be inflicted during the surgical procedure, and a pelvolithotomy should be performed whenever possible.

TYPE OF STONES

The surgical removal of a branched stone extending into the calices is more likely to be followed by a recurrence than when a smaller stone is removed which is confined to the pelvis of the kidney. This may be due to injury of the calix or infundibulum, allowing blood clots to remain behind, subsequent development of stricture of the infundibulum which is conducive to stasis in the calix and later infection, or a small stone or fragment of a stone may be overlooked in one of the calices.

It is apparent that the removal of multiple calculi from the kidney is attended by a greater increase of recurrence than when a solitary stone is removed. Frequently a small calculus or a fragment which may not even be discernible on the roentgenogram has been removed by a suction apparatus which we employ as a routine following the removal of a stone from the kidney. Similarly, if a coexisting infection is present in the kidney, especially of a staphylococcus or proteus bacilli, the incidence of recurrence following operation is more than when culture of the urine is sterile.

In a similar manner, stones of soft consistency are more prone to be followed by a recurrence, possibly because sand remains to act as a nucleus for secondary formation. After removal of a calculus from the kidney, thorough lavage of the calices and pelvis followed by suction with the apparatus I have previously described will minimize the incidence of recurrent stone formation.

SURGICAL ASPECTS OF PREVENTION

There is little doubt that the surgical procedure which is accompanied by a minimum degree of trauma to the kidney is preferable. I do not believe that as a routine the kidney should be manhandled, traumatized and delivered into the incision in removing a stone from its pelvis. Rather, the operative procedure should be carried down to the pelvis of the kidney and adequate exposure secured by use of flexible retractors without delivering the kidney. In instances in which there is no coexisting renal infection or, if it is not pronounced, the incision in the pelvis should be closed with triple 0 catgut sutures passing only through the outer coats of the pelvis and not through the mucosa, where it might be retained and act as a nucleus for a recurrent calculus.

Joly³¹ has stated that even temporary leakage of urine increases the risk of recurrence of stone and should be avoided if possible. He likewise believes that if the kidney has been drained it is usually found to be infected with *Staphylococcus albus*. Similarly, Rovsing¹⁰ has stated that urinary leakage of only a few days duration is sufficient to infect the kidney. In cases, however, in which a pronounced infection is present, it may be advisable to perform a nephrostomy, or a catheter may be left directly in the pelvis to permit lavage and facilitate adequate drainage.

Nephrolithotomy is employed only when pelvolithotomy does not seem feasible. In all cases it should

be as conservative as possible. When a calculus is confined to a calix and the infundibulum is too narrow to permit its extraction through the pelvis, a localized nephrolithotomy is advisable. Again, in the removal of staghorn stones, nephrolithotomy may be necessary, and I believe that adequate drainage should be instituted in these cases.

A pelvonephrolithotomy, in my experience, is seldom necessary, and only if technical difficulties arise.

A heminephrectomy may be the preferable operative procedure in some instances in which a calculus is confined to a large, dilated calix. In the presence of a stricture of the infundibulum and infection of the calix, the latter can be eradicated only by this procedure, and fewer recurrences will follow this method than if a localized nephrotomy is done. Likewise, the remaining portion of the kidney is saved from the ravages of infection.

Fig. 8.—Recurrent renal and bladder calculi in a patient with cystinuria.

Again I wish to stress the importance of thoroughly lavaging the pelvis and calices followed by the use of a suction tube again placed in the pelvis and calices to remove clots, debris, fragments of stones or minute stones and sand that might be overlooked.

CONCLUSIONS

It is apparent that many factors may be associated with the formation of recurrent renal calculi. An intensive preoperative investigation is required in each individual case to ascertain the factor or factors instrumental in the production of the primary calculus. Their correction and eradication at the time of operation or in the postoperative routine is rewarded by a reduction in the incidence of recurrence. In addition to eradication of the various etiologic agents, control of the p_H of the urine by the high vitamin A acid ash or alkaline ash diet, depending on the chemical constituents of the stone removed at the time of operation, has been attended by a pronounced decrease in the incidence of recurrent formation of calculus in our hands.

CALCIUM AND PHOSPHORUS EXCRETION IN THE URINE

OF PATIENTS WITH RENAL OR URETERAL CALCULI

R. H. FLOCKS, M.D.

IOWA CITY

Many workers have indicated the possibility that the increased urinary concentration of calcium and phosphorus associated with certain generalized conditions such as hyperparathyroidism,¹ bone disease and fractures² may be an important factor in calcium urolithiasis. However, little quantitative work on this concentration in patients with urinary calculi is available.

Since on theoretical, experimental³ and clinical grounds it would seem that increased urinary concentration of calcium and phosphorus should be an important factor in the formation of stone, it was felt that a quantitative study of the urinary calcium and phosphorus in all types of patients with calcium urolithiasis and the quantitative differences in this factor as the result of treatment would be of significance from an etiologic, prognostic and therapeutic point of view. It is my purpose in this paper to present the results of such a study in a series of thirty-five consecutively admitted patients with renal or ureteral calculi.

SUBJECTS

Thirty-five consecutively admitted patients with calcium stones in the kidneys or ureters form the basis of this study. Their ages ranged from 19 to 70 years, but the vast majority were from 20 to 40 years of age. Twenty-two of them were men and thirteen were

the late stages of Paget's bone disease. Only one presented vitamin A deficiency, although twenty of them were studied by means of the Jeans biophotometer test. This deficiency was speedily rectified by the administration of vitamin A. Two patients presented hyperparathyroidism, as evidenced by increased serum calcium, decreased serum phosphorus and increased urinary calcium. Neither had bone changes. A parathyroid adenoma was subsequently removed from one of them. Four months after operation this patient continued to excrete large quantities of calcium in the

Fig. 2.—Urinary excretion of calcium and phosphorus by a white woman aged 43 with left renal stone. There was a history of hyperthyroidism with subtotal thyroidectomy eleven years previous to admission. At present the patient has essentially normal urinary excretion of calcium and phosphorus. Compare this response to the fixed diets with that illustrated in figure 1.

Fig. 1.—Urinary excretion of calcium and phosphorus by a white man aged 21 with a calcium oxalate stone in the right ureter. The pH of the urine was 5.5. At the present time the patient shows very high urinary excretions of calcium on both low and high intakes. Note that the excretion of phosphorus is also moderately increased, but not as markedly as the calcium. Compare this response to the fixed diets with that illustrated in figure 2.

women. All of them except one, who had generalized atrophic arthritis, were ambulatory during the course of the studies. Of the ambulatory patients, one was in

urine, although the blood calcium and phosphorus levels, which had returned to normal immediately after operation, were still normal. The other patient refused operation, so that direct proof of parathyroid disease was lacking. All the patients suffered from some slight infection of the urinary tract, as evidenced by the finding of an occasional pus cell in the urine, but none of them had outspoken urinary sepsis. Organisms were found in the urines of all patients. These were *Staphylococcus albus* and *aureus*, *Bacillus proteus*, *Bacillus coli* and *Staphylococcus haemolyticus* either alone or together. No fevers, colds or other intercurrent infections were noted. In addition, twelve volunteers without any evidence of stone or other abnormalities were used as controls.

METHODS AND RESULTS

Metabolic studies including accurate weighing and analysis of all food and water ingested and of all urine excreted were carried out on each patient. Since four different methods of attack were used, the individual methods will be described in the appropriate section.

EFFECT OF DIETS WITH HIGH AND WITH LOW CALCIUM AND PHOSPHORUS CONTENT AND WITH NEUTRAL ASH

In order to ascertain whether or not there is an excessively high concentration of calcium and/or phosphorus in the urine of patients with calculus, each of the thirty-five subjects as well as the twelve normal volunteers was placed successively on (a) a diet low in calcium and phosphorus, with a daily intake of 0.3 and 0.8 Gm. respectively and producing a neutral ash and (b) a diet high in calcium and phosphorus with a daily intake of 2.5 Gm. of each and producing a neutral ash. Each diet was fed identically to each patient and control for a six day period. The daily fluid intake was identical for each subject and control and was limited to 2,000 cc.

From the Department of Urology, State University of Iowa College of Medicine.

Read before the Section on Urology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 19, 1939.

Dr. N. G. Alcock of the Department of Urology and Dr. Kate Daum of the Department of Nutrition of the State University of Iowa College of Medicine gave the author valuable aid and discussed this subject with him during the course of this study.

3. Keyser, L. D.: Recurrent Urolithiasis: Etiologic Factors and Clinical Management, *J. A. M. A.* 104: 1299 (April 13) 1935.

Repeated studies of seven patients were made at intervals of several months and in each instance the results were essentially the same.

In eleven of the control group of twelve volunteers the average calcium excretion, as might be expected, varied with the diet, being from 100 to 150 mg. a day on the low intake and from 250 to 300 mg. a day on the high intake. One of the "normal" controls showed an excretion of 220 mg. of calcium a day on the low intake and 460 mg. on the high intake.

The thirty-five patients with stone, however, very definitely divided themselves into two groups (figs. 1 and 2): Group 1, a large one consisting of twenty-three of the thirty-five patients, showed an increased or high urinary excretion of calcium; group 2, a comparatively small one consisting of twelve of the thirty-five patients, showed either a normal or a low urinary excretion of calcium. The phosphorus excretion in all the patients, with one exception, was essentially normal for each diet. The one exception showed a high phosphorus excretion associated with a high calcium excretion.

All of the first group of twenty-three patients excreted more than 420 mg. of calcium a day on the diets rich in calcium and phosphorus, and a daily cal-

To review, then, in a group of thirty-five patients with urinary calculi twenty-three showed excessive excretion of calcium in the urine. Because the excess over normal was exaggerated on the high intake, this excessive excretion could be demonstrated most readily by noting the response of the urinary calcium to the

Fig. 3.—Urinary excretion of calcium by a white man aged 28 with a right renal calculus. The stones were calcium phosphate. Urinary calciums were studied repeatedly over a period of eighteen months and remained persistently high, while urinary phosphorus remained normal. Note the marked increase in urinary calcium when vitamin D in moderate doses was added to the neutral ash diet low in calcium and phosphorus.

cium excretion of more than 600 mg. was not uncommon. These values are comparable to those seen in hyperparathyroidism. Twenty-one of these patients excreted more than 200 mg. a day, but the remaining two excreted less than 200 mg. on the low intake diets. Both of the patients with hyperparathyroidism were in this group of subjects with excessive output of urinary calcium. Moreover, it is of especial interest that all those patients (ten of the thirty-five) with rapidly developing stones or with rapid formation of new stones fell into this group.

Of the group of twelve patients with normal or subnormal urinary excretion of calcium three presented a history which suggested that at the time when the urinary calculi originated there was probably an increased urinary excretion of calcium or phosphorus. There was neither a history nor indications in the remaining nine cases to suggest such a contingency. However, in none of these cases at the time these studies were made was there evidence of rapid growth of stones or of new formation of stones, and in three of them kidney stone had been known to be present and quiescent over a period of years.

Fig. 4.—Appearance of plain x-ray film in a case of right renal stone in a white man aged 64.

high calcium and phosphorus intake. Only two of these twenty-three had hyperparathyroidism. In the other twenty-one no definite reason for the excessive urinary calcium was to be found. Moreover, all patients showing rapidly forming stones or new stone formation while under observation showed high urinary calcium excretion. Also of the twelve patients with a low urinary

Fig. 5.—Excretory pyelograms of same patient as in figure 4. Note that there is good renal function bilaterally with practically no distortion of the right pelvis. The calcium concentrations in the kidney urines were 36 mg. per hundred cubic centimeters on the right and 18 mg. on the left. The phosphorus concentrations were 76 mg. on the right and 43 mg. on the left.

calcium three gave a history of a condition associated with increased urinary calcium at the time when the urinary calculi probably originated. Thus a marked increase in excretion of urinary calcium was demonstrable at one time or another in twenty-six of the thirty-five subjects with urolithiasis.

THE EFFECT OF DIETS WITH AN ACID ASH

The fact that calcium phosphate does not precipitate readily at a low urinary p_H has caused many workers⁴ to emphasize the necessity of keeping the urinary p_H low in these patients in order to prevent recurrence of renal calculi and possibly dissolve a certain number of them. For this reason diets with a high acid ash supplemented by substances such as ammonium chloride and ammonium nitrate have been advocated. However, Albright⁵ and others⁶ have emphasized the fact that the ingestion of acid-forming substances usually is associated with an increased calcium excretion in the urine. This, of course, would tend to neutralize the effect of the lower p_H . Therefore, in order to estimate this relationship quantitatively we studied the effect of an acid ash diet and ammonium chloride in both groups of patients, i. e. in the group with excessive urinary calcium excretion and in the group with the essentially normal or low urinary excretion of calcium. When the group with the high urinary calcium excretion was placed on an acid ash diet supplemented by 4 Gm. of ammonium chloride daily, a marked increase in urinary calcium was obtained. Thus on an acid ash diet containing 0.8 Gm. of calcium daily urinary excretions of from 400 to 450 mg. of calcium a day were obtained. In contradistinction, the group presenting the low urinary calcium showed low responses to the same diet

Fig. 6.—Appearance of plain x-ray film in a case of a normal right urinary tract and a left hydro-ureter and hydronephrosis due to a congenital stricture at the ureterovesicular junction in a white man aged 24.

and medication. Values of from 200 to 250 mg. of calcium in the urine per twenty-four hours were obtained. This is of considerable import in the treat-

ment of patients with renal stones by means of the acid ash diet. In the first group, the group showing high urinary calcium, relatively little or no beneficial effect is to be expected from the acid ash diet. Moreover, if urea-splitting organisms are present in the urine or the slightest amount of stasis is present harmful effects,

Fig. 7.—Retrograde pyelogram of same patient as in figure 6. Note that there is present a gradually enlarging left renal calculus. There is good function bilaterally. The calcium concentrations in the kidney urines were 8 mg. per hundred cubic centimeters on the right and 14 mg. on the left. The phosphorus concentrations were 8 mg. on the right and 9 mg. on the left.

such as were obtained by Oppenheimer and Pollack,⁷ may result. In contrast, in the second group of patients, those showing a low urinary calcium and a low urinary calcium response to the acid ash diet, this type of diet is ideal if the desired urinary p_H can be obtained.

EFFECT OF DIETS SUPPLEMENTED BY VITAMIN D

A great many of the preparations of vitamin A are at present combined with vitamin D. Experimentally vitamin D is known to produce an increased urinary excretion of calcium. I have, therefore, studied the urinary calcium and phosphorus excretion in normal persons and also some of the patients who showed an increased urinary calcium output. The number of patients in whom complete studies were made is still quite small. However, all the patients with an increased urinary calcium excretion and renal calculi when placed on moderate doses of vitamin D showed an excessive urinary calcium response. This response was much more marked than that obtained in the normal volunteers. This finding is similar to the observations of Mawson,⁸ who studied the urinary excretion of calcium in a group of tuberculous patients receiving heliotherapy (fig. 3).

4. Higgins, C. C.: Production and Solution of Urinary Calculi, *J. A. M. A.* 104: 1299 (April 13) 1935.

5. Albright, Fuller; Baird, P. C.; Cope, Oliver, and Bloomberg, Esther: Studies on the Physiology of the Parathyroid Glands: IV. Renal Complications of Hyperparathyroidism, *Am. J. M. Sc.* 187: 49-65 (Jan.) 1934.

6. Barney, J. D., and Sulkowitch, H. W.: Progress in Management of Urinary Calculi, *J. Urol.* 37: 746-762 (June) 1937.

8. Mawson, E. E.: A Consideration of Some Possible Factors Concerned in the Development of Urolithiasis in Children, *Liverpool Med. Chir. J.* (pt. 2) 40: 99-133, 1932.

These significant quantitative differences in urinary calcium following the administration of high acid ash and vitamin D intakes illustrate the necessity of studying in each individual patient that patient's response to the therapy that is being instituted.

EFFECT OF URINARY STASIS

In order to ascertain the effects of urinary stasis and of other diseases of the urinary tract on the urinary excretion of calcium, studies were made on urine obtained by simultaneous catheterization of each ureter (figs. 4-9). In this way the normal kidney acted as a control for the pathologic one. Fourteen patients were studied in this manner. Although it is difficult to draw conclusions from so small a group, the trend is definite. Apparently a slight or intermittent obstruction or a slight to moderate pathologic process in the urinary tract, such as the presence of a small stone in the kidney pelvis, was associated with a significantly higher calcium concentration in the urine from that kidney than in the urine from the normal kidney. At times this concentration of calcium in the urine was twice that found in the normal mate. In contrast, complete obstruction or marked destruction of the kidney substance was always associated with a reduced calcium concentration. These observations are consistent with those of Hunner⁹ and others as to the relation of stasis to urinary stones. Moreover, they emphasize the danger that a new nucleus may be formed in the kidney substance during the time consumed while waiting for a kidney stone to pass spontaneously. Also they may account for unilateral stone formation in the group of patients with a tendency to excessively high urinary calcium.

EFFECT OF VARIATION OF FLUID INTAKE

Corresponding to the results obtained by Albright, we found that the total daily urinary calcium excretion

Fig. 8.—Appearance of plain x-ray film in a case of one large and several small right renal calculi in a white man aged 45.

was quite independent of the water excretion, so that increased output of water merely diluted but did not change the calcium and phosphorus output. Therefore, the most satisfactory method for decreasing urinary calcium and phosphorus concentration is the intake of large quantities of water.

COMMENT

Two groups of factors may be considered as fundamental in the pathogenesis of renal stone: (1) those factors which so change the nature of the renal substance as to favor precipitation of the crystalloids within it and (2) those factors which favor the precipitation

Fig. 9.—Retrograde pyelogram of same patient as in figure 8. Note that renal function was very much decreased on the right side. The concentrations of calcium in the kidney urines were 6 mg. per hundred cubic centimeters on the right and 16 mg. on the left. The concentrations of phosphorus were a trace on the right and 10 mg. on the left.

of crystalloids in the urinary passageway. In any individual patient either or both groups of factors may be operating at the same time or at different times.

Damage to the kidney substance predisposing to the precipitation of crystalloids is of importance in many cases. However, the exact factors that produce this type of damage with the associated precipitation of calcium salts are not known. Randall¹⁰ has demonstrated subepithelial plaques of precipitated calcium which formed a nucleus for stone formation. Hellstrom, Huggins¹¹ and others¹² have demonstrated similar lesions and precipitations within and about the tubules and so-called microliths in kidneys associated with renal calculi. Precipitations of this sort appear experimentally and clinically in vitamin D "poisoning" and in hyperparathyroidism.¹³ In both these conditions there is an increased urinary calcium excretion. This excessive excretion may be the underlying factor, or at least a very important factor, in the formation of these calcium deposits. Higgins⁴ and others have established the fact that there is a definite relationship between vitamin A deficiency and stone formation. Vitamin A deficiency may act by destroying the vitality of the renal epithelium, thus permitting precipitation of calcium and phosphorus within it. Infection in the renal pelvis itself and obstruction to the outflow of urine from the pelvis may likewise damage the kidney substance. In this clinic twenty-one of a series of fifty-three kidneys in which renal stone was or had been present were found to have microscopic deposits of calcium within the tubules or the tubular epithelium, or microliths as

11. Huggins, C. B.: Bone and Calculi in the Collecting Tubules of the Kidney, Arch. Surg. 27: 203-215 (July) 1933.

12. Craibtree, E. D.: Calcification Within Tubules of Kidney in Association with Urinary Tract Lithiasis, Tr. Am. A. Genito-Urin. Surgeons 23: 17, 1930.

13. Albright, Fuller, and Bloomberg, Esther: Hyperparathyroidism and Renal Disease, J. Urol. 3: 1-7 (July) 1935.

described by Randall, Hellstrom, Huggins and others. These lesions are strikingly similar to the lesions described in hyperparathyroidism, vitamin D "poisoning" and experimental stone production by hyperexcretion of crystalloids (Keyser¹⁴). Thus precipitations of crystalloids in the kidney substance of each individual patient may be produced by any one or any combination of the following factors: toxins, vitamin A deficiency, vitamin D poisoning, hyperparathyroidism, increased urinary calcium and phosphorus due to other causes, infection in the renal pelvis or urinary tract obstruction.

The two fundamental factors determining the precipitation or solution of calcium and phosphorus in the urinary passageways are the urinary p_H and the urinary concentration of calcium and phosphorus. Certain accessory factors may also be of importance: the colloids of the urine, the surface tension of the urine, the presence of stasis and the presence of bodies that might act as nuclei for the precipitation of crystalloids. The importance of the hydrogen ion concentration and the ease with which this concentration can be changed to the alkaline side by urea-splitting organisms, together with the marked frequency with which these organisms occur in patients with renal calculi, has been demon-

previous paragraphs, increased excretion of calcium and phosphorus in the urine may be of importance in both groups of factors.

The high incidence of increased urinary calcium in the thirty-five cases of calcium urolithiasis described in this report emphasizes the relationship between urinary calcium and the pathogenesis of renal calcium stones. Moreover, the fact that twenty-one of these patients showed no evidences of hyperthyroidism, hyperparathyroidism or bone disease emphasizes the fact that high urinary calcium may be present in these patients and must be considered in their prognosis and treatment even though conditions usually associated with increased urinary calcium are absent.

It would seem that, although the high concentration of the calcium in the urine of itself is not enough to bring about precipitation in the kidney substance or in the urinary passageway, it would predispose these patients to this occurrence. Therefore, given a patient or an otherwise normal person with a high urinary calcium, other factors being equal, he would be more likely to form stone than one with a low urinary calcium. For example, given two persons with infection of the urinary tract presenting urea-splitting organisms, the question as to the one who will form stone may depend on the urinary concentration of calcium. Similarly in deciding which patient will have a recurrence of stone following operative removal of urinary calculus, other factors being equal, urinary concentration of calcium will be the deciding factor.

Moreover, because of this relationship between urinary calcium excretion and urolithiasis, conditions that are associated with increased urinary calcium need complete quantitative study from this angle. When does the increased urinary calcium occur? How can it be modified? (fig. 10). In this way information may be obtained which will be of importance in the prevention of the occurrence and recurrence of calcium stone in the urinary tract.

The urinary calcium is of importance not only from an etiologic point of view but also from a prognostic and therapeutic point of view. The results of these studies emphasize the necessity of studying quantitatively the calcium excretion in the urine under different types of therapy instituted. They show that when increased urinary calcium is found the prognosis is poor and that acid ash diets and vitamin D should be used with care. Marked dilution of the urine should be sought for and all possible sources of this high urinary calcium searched for and eliminated. In contrast, in patients with low urinary calcium the prognosis is better and beneficial effects may be expected from acid ash diets. Moreover, in considering the problem of recurrence of stone in a particular kidney, the possibility of altered urinary excretion of calcium through that particular kidney is of importance.

SUMMARY AND CONCLUSIONS

1. A study was made of the urinary excretion of calcium and phosphorus under fixed conditions in a group of thirty-five patients with renal calculi. In twenty-three patients of this series high urinary calcium excretion was found. In three of the twelve with low urinary calciums there was a history suggesting increased urinary excretion of calcium at a time when the calculi probably started. Only two of these patients had clinical evidences of hyperparathyroidism.

2. All the patients with rapidly growing stones or new stone formation during observation were in the group presenting the high urinary excretion of calcium.

Fig. 10.—Urinary excretion of calcium and phosphorus by a patient with a fracture of the left femur of a week's duration. The patient is bedridden with the left lower extremity immobilized. Note the high urinary calcium response to the low intake.

strated by many workers. Experimentally the importance of the increased concentration of crystalloids in the urine has been emphasized by Keyser. The high incidence of urinary stone in hyperparathyroidism, in which increased urinary excretion of calcium and phosphorus occurs, has been emphasized by Albright and Barney. The high incidence of urinary calculi in patients with bone disease, in whom presumably there is some alteration in calcium metabolism probably associated with increased calcium excretion, has been emphasized by Holmes and Coplan and by Jones and Roberts and others. Steiner¹⁵ has demonstrated that the epithelial desquamation which occurred in vitamin A deficiency may act as a nucleus for the precipitation of crystalloids. Again there is a multiplicity of factors one or more of which may be present in each patient.

There are, then, two groups of factors in the pathogenesis of renal stone: first, those factors which are associated with the precipitation of crystalloids in the kidney substance and, second, those which are associated with the precipitation of the crystalloids in the urinary passageway. Moreover, as discussed in the

¹⁴ Keyser, L. D.: The Mechanism of the Formation of Urinary Calculi, *Ann. Surg.* 77: 210 (Feb.) 1923.

¹⁵ Steiner, Morris; Zugar, Bernard, and Kramer, Benjamin: Production of Renal Calculi in Guinea Pigs by Feeding Them a Diet Deficient in Vitamin A, *Arch. Path.* 27: 104 (Jan.) 1939.

3. The patients with high urinary calciums responded to an acid ash diet with an excessively increased urinary calcium as compared to the patients with low urinary calciums.

4. The patients with high urinary calcium responded to a moderate vitamin D intake with an excessively increased urinary excretion of calcium as compared to normal volunteers.

5. A study of the effect of pathologic changes in the kidney on the urinary excretion of calcium through that kidney was made in fourteen patients. A slight pathologic change was usually associated with definitely increased urinary calcium as compared with the normal mate; marked pathologic change was usually associated with definitely lowered urinary calcium as compared to the normal mate.

6. Increased fluid intake resulting in increased urinary output merely seemed to dilute the urine and thus reduce calcium concentration per unit volume. It did not alter significantly the total daily amount of calcium excreted.

7. Consequently, in the management of patients with urinary calculi it is important to consider not only such factors as vitamin A deficiency, infection of the urinary tract, hyperparathyroidism and stasis but also the quantitative urinary concentration of calcium and the quantitative influence on this concentration of any treatment instituted.

DO ALKALIS USED IN THE TREATMENT OF PEPTIC ULCER CAUSE KIDNEY STONES?

A STUDY OF 1,940 CASES

HERMAN L. KRETSCHMER, M.D.

AND

RALPH C. BROWN, M.D.

CHICAGO

The occurrence of urinary calculus in a patient who for a period of time has been taking alkalis in the treatment of peptic ulcer may arouse suspicion that the stone has formed as a result of the use of the alkalis. This idea appears to exist not only in the minds of the public but in the minds of some members of the medical profession as well.

The present study was undertaken with a view of securing data from which conclusions might be drawn as to the etiologic relationship, if any, between the use of alkalis in the treatment of peptic ulcer and kidney and ureteral stone formation.

The data that we present were obtained by an examination of the records of 2,210 cases, of which 1,260 cases were seen by one of us (H. L. K.) and 950 by the other (R. C. B.).

HISTORY

Calculus disease dates back to the very beginning of civilization. According to Joly,¹ the earliest specimen of a vesical stone was discovered by Prof. Elliott Smith in the grave of an Egyptian and was estimated to be about 7,000 years old. It was composed of a central nucleus of uric acid surrounded by a thick layer of

calcium oxalate and ammonium-magnesium phosphate. He also described another stone which was found lying close to the second lumbar vertebra of a skeleton in a tomb, dating from the second dynasty about 4100 B. C. It was composed of carbonate, phosphate and oxalate of lime. From its appearance and the position in which it was found it was supposed to be a renal calculus.

The chemical composition of these stones bears a striking resemblance to the composition of kidney and ureteral stones that occur today, and one may say that through the past 7,000 years there has been no great change in the chemical composition of these calculi.

Randall² has recently published the results of the chemical examinations of a large series of kidney and ureteral stones. Attention may be called to the large number of kidney stones that were composed of pure calcium-magnesium phosphate, thirty-nine of seventy-one, or 54 per cent. We wish also to direct attention to the fact that of 100 cases of stone in the ureter in which the stones occurred in pure salts, forty-nine of them consisted of pure calcium-magnesium phosphate.

Before entering into a discussion of the question of the possible relationship between the use of alkalis in the treatment of peptic ulcer and the formation of kidney stones, it might be well to present briefly the various theories as to the origin of these stones. At the outset it might be well to call attention to the statement of Hinman, who says "No more is known of what starts the mechanisms of formation of stone than of the mechanism itself." Attention may also be called to the statement of Howard Kelley: "No stretch of chemical or physiological imagination will permit so heterogeneous a group of compounds to be ascribed to a common origin, or their deposition, in kidney, ureter or bladder, to be uniformly charged to an identical cause."

Since the treatment of peptic ulcer is intimately associated with a definite dietary regimen, it might be well to state at the outset that all patients are on a program designed to exclude the possibility of vitamin deficiency, so that avitaminosis as a factor can be excluded.

Experimental studies have been presented demonstrating a relation between deficiency of vitamin A and the production of urinary calculi in animals. Contributions on this subject have been furnished by McCarrison,³ Fujimaki,⁴ van Leersum, Perlman, Higgins,⁵ Steiner, Zuger and Kramer⁶ and many others. They agree that the vitamin A deficiency is often the cause of urinary calculi in experimental animals.

Furthermore, attention may be called to the fact that the incidence of urinary stone in children, especially bladder stone, has almost disappeared since the institution of modern diets which prevent avitaminosis.

During the past ten years a good deal of attention has been given to disturbance in the function of the parathyroids. Although renal calculi are found in hyperparathyroidism, it is doubtful whether it plays a role in the production of renal calculi as seen in practice.

Albright, Baird, Cope and Bloomberg⁷ reported that 27 per cent of a series of eighty-three patients with hyperparathyroidism had renal calculi. On the other

hand, Braasch, Griffin and Osterburg in a study of 1,206 consecutive cases of urolithiasis found hyperparathyroidism as an etiologic factor in less than 0.2 per cent.

Albright and Bloomberg⁸ concluded that formation of urinary calculus in hyperparathyroidism belongs to that etiologic group in which the predisposing abnormal factor is an excess of crystalloids in the urine.

Disturbance in the colloid-crystalloid balance as a cause of renal stone was proposed many years ago. It is based on the assumption that the urine is a supersaturated solution and that the crystalloids are held in solution because of the presence of protective colloids. Precipitation of crystalloids may occur if they are present in so excessive an amount that the normal colloid cannot hold them in solution or if they are present in normal amount and there is a diminished amount of colloids present.

Interesting in this connection is the fact that some patients have an excessive amount of crystalloids in the urine and yet stone never develops. As examples, cystinuria, oxaluria and phosphaturia may be mentioned.

The theory that interference with urinary drainage results in stasis and hence predisposes to stone is an old one. In cases of hydronephrosis with stone formation one is always confronted with the question of

types of treatment, such as Leube's and Leuhartz's, came into vogue, the employment of alkalis was a definite part of the regimen.

In 1914 Sippy proposed the use of acid neutralizing substances, chiefly alkalis and milk, to be taken with a frequency and in amounts sufficient to effect complete neutralization of the free hydrochloric acid in the gastric content from morning until night. The validity of the basic principle of the Sippy treatment, namely, freeing the exposed surface of the peptic ulcer from the tissue digesting action of the gastric juice by inhibiting its proteolytic action, as can be done by total neutralization of hydrochloric acid, has been well established in the intervening years.

As is true with most useful chemical therapeutic agents, alkalis must be used with a certain amount of discretion. Persons differ in their tolerance of various types of alkalis just as they differ in their tolerance of belladonna and other substances. In general, older persons tolerate them less well than the young and the middle aged. Many different alkaline substances have been employed, chiefly sodium bicarbonate, calcium carbonate, magnesium oxide and the tribasic phosphates of calcium and magnesium, and of these the latter three are apparently the least likely to cause an acid-base imbalance.

In the ulcer cases covered by this survey the group in the earlier years was treated with sodium bicarbonate and calcium carbonate. In the last ten years the tribasic phosphates of calcium and magnesium have been most commonly used in the treatment of ulcer at the Presbyterian Hospital. The amount required in the individual case is determined by aspiration of gastric contents and titration. The total daily amount of the tribasic phosphates used varies from 25 to 30 Gm. for periods varying from two to six months. If any symptoms indicative of disturbance of the acid-base ratio develop, the further use of alkaline salts is governed by estimation of the carbon dioxide of the blood plasma. Special attention is given to the vitamin requirements of these patients.

It has been claimed that the administration of alkalis in the treatment of peptic ulcer may cause certain disturbances in the calcium and inorganic phosphorus content in the blood serum. In order to determine whether or not there is any disturbance of the calcium phosphorus blood level, twenty-five cases of peptic ulcer under thorough alkalization were studied to determine the serum calcium and serum phosphorus content. The highest calcium figure was 12 mg. per hundred cubic centimeters, the lowest 9.3 mg. and the average 10.38 mg. The highest inorganic phosphorus content was 4.4 mg. per hundred cubic centimeters, the lowest 2.8 mg. and the average 3.65 mg. As the highest figures obtained are within the normal range and the averages are quite normal for both calcium and phosphorus, it would seem that the use of alkalis in ulcer treatment does not predispose to stone formation through elevation of blood serum calcium and phosphorus.

For the purpose of this investigation a detailed study of the records of 950 cases of peptic ulcer was made. These were taken from the files of the Presbyterian Hospital without selection but included a group of cases from each year from 1914 to 1937 inclusive.

A questionnaire was directed to this group of 950 patients, of whom 680 replied, and the data to be presented is based on the replies received from this group of 680 peptic ulcer patients who had had treatment for

TABLE 1.—Location of Stone in Seven Cases

Case	Age	Sex	Location of Stone
1	43	♀	Kidney
2	40	♂	Ureter

5	45	♂	Kidney
6	47	♂	Ureter
7	48	♂	Kidney

whether the stone made the hydronephrosis or vice versa. Although stasis may play a role in some cases, it can hardly be called on as a factor in the very large number of cases in which stasis is absent.

There can be no doubt that infection plays an important role in a certain number of cases. On the other hand, the large number of cases of stone without infection immediately raises the question of the role played by infection in each case. Furthermore, the common cause of renal infection is the colon bacillus; the largest number of infections are not associated with stone.

The recent work of Randall is extremely interesting in this connection. According to him, renal calculus formation is dependent on a preexisting renal lesion, and this lesion consists of the deposition of calcium in the walls and intertubular spaces of the renal papillae. He believes that these calcium plaques appear to be a natural reparative process to some form of tubular damage. He was able with seven specimens to show a calculus attached to the calcium plaque.

THE RATIONALE OF ULCER TREATMENT

The use of alkaline substances in the treatment of peptic ulcer is more ancient than our knowledge of the lesion. Long before Baillie's description of the morbid anatomy and symptoms of gastric ulcer in 1793 and Cruveilhier's classic work some years later, sufferers with ulcer had learned that relief from the gnawing pains of ulcer could be had by taking chalk, magnesium and sodium bicarbonate. When the early standard

8. Albright, Fuller, and Bloomberg, Esther: *Tr. Am. A. Genito-Urin. Surgeons* 27: 195, 1934.

periods of from three to six months, the average period of accurate treatment being four months in duration. Many of these patients reported that they took minor amounts of alkaline powders over a much longer period.

INCIDENCE OF RENAL AND URETERAL CALCULI IN
680 CASES OF PEPTIC ULCER TREATED WITH
MILK AND ALKALIS

An interesting fact that was brought out in this study is that twenty-one patients gave a history of urinary calculus before they presented themselves for diagnosis and treatment of peptic ulcer. By contrast, there were only thirty-three cases in which there was a history of urinary calculus that occurred sometime after the treatment of peptic ulcer was instituted.

In many of these cases symptoms of kidney stone developed from ten to twenty years after the treatment for ulcer had been discontinued. Furthermore, it must be borne in mind that a large proportion of this group of 680 ulcer cases had been treated from ten to twenty-five years prior to the period of this inquiry; hence in an evaluation of the data consideration must be given to the fact that in any such cross section of the population as represented by this group of 680 individuals—a majority of them now in middle or later life—a certain normal incidence of renal calculus is certain to exist.

Also in certain of these thirty-three cases of calculi occurring after ulcer treatment there may well have been an unrecognized, symptomless kidney stone at the time of institution of ulcer treatment, since the passing of stones within two months thereafter was reported in some cases. The spontaneous passage of a single small stone was reported in six of the thirty-three cases.

Summarizing the facts brought out by this study of 680 ulcer cases under treatment, there were twenty-one (3.1 per cent) in which stones occurred before ulcer treatment and thirty-three (4.9 per cent) in which stones occurred after ulcer treatment. Hence, even if the modifying factors previously mentioned (i. e., normal incidence of stone) are disregarded, it would seem that the case against alkalis as used in ulcer treatment as a cause of renal calculus narrows down to the difference between the 4.9 per cent of cases in which stone was reported after treatment and the 3.1 per cent of cases in which stones were reported before ulcer treatment, a difference of 1.8 per cent; not a grave indictment of the use of alkalis.

As an approach to this problem from the urologic point of view, the records of 1,260 cases were studied, supplemented by many personal interviews.

In this series of 1,260 cases of renal and ureteral calculi there were seven in which the diagnosis of stone and ulcer was made simultaneously and in which there had been no ulcer treatment. This group of cases is presented in table 1.

It is interesting to note that six of the seven cases occurred in men and that all seven cases occurred in the fourth decade.

Among the 1,260 cases were twenty-six in which there was a history of peptic ulcer, or 2.06 per cent. The age, sex, location of the stone and treatment carried out are given in table 2.

An analysis of this group shows that only fifteen patients, or 57.692 per cent, received alkalis for the treatment of ulcer. Seven of the remaining eleven patients, or 26.923 per cent, received surgical treatment. The operations performed were gastro-enterostomies and gastric resections. One of the patients had three

operations for ulcer, namely a gastro-enterostomy, a gastrojejunostomy and finally a resection. The remaining four patients, or 15.384 per cent, received no alkalis in the treatment for peptic ulcer.

Since some of the patients were treated elsewhere for ulcer, the thoroughness with which the treatment was carried out as far as the amount of alkalis used is concerned may be open to question.

We wish to call attention to the fact that, of the fifteen cases in which alkalis were given, in three the stones occurred many years after the ulcer treatment was discontinued. In one instance the stone developed fourteen years later, in another ten years and in the third case five years later.

Because of the long period that elapsed between the cessation of ulcer treatment and the onset of the urinary calculi, one may question the relationship, if any, between the two and state that the occurrence of the stones so many years later was purely incidental.

TABLE 2.—Location of Stone and Treatment in Twenty-Six Cases of Peptic Ulcer

Case	Age	Sex	Location	Treatment
1	54	♀	Ureter	Alkalis
2	59	♂	Kidney	Gastro-enterostomy only
3	38	♂	Kidney (bilateral)	Alkalis
4	57	♂	Kidney	No treatment
5	59	♂	Kidney	Alkalis
6	41	♀	Kidney	Resection, stomach
7	62	♂	Kidney	No alkalis, milk and cream only
8	67	♂	Kidney	Gastro-enterostomy
9	53	♂	Kidney	Laparotomy for ulcer
10	57	♂	Kidney	No alkalis, milk only
11	55	♂	Kidney	Gastro-enterostomy + treatment
12	44	♀	Kidney	Alkalis
13	73	♂	Kidney	Alkalis
14	47	♂	Kidney	Alkalis
15	61	♂	Kidney	Alkalis
16	54	♂	Kidney	Gastro-enterostomy
17	38	♂	Kidney	Alkalis
18	70	♂	Ureter	Alkalis
19	52	♂	Ureter	Alkalis
20	45	♀	Ureter	Alkalis
21	41	♂	Ureter	Alkalis
22	68	♂	Ureter	Alkalis
23	35	♂	Ureter	Alkalis
24	27	♂	Ureter	Three operations for ulcer of stomach
25	39	♂	Ureter	Alkalis
26	68	♂	Kidney and ureter	No alkalinization; soda once in a while

These stones were small and were passed by the patient or removed by cystoscopic manipulation.

It is interesting to note that some of the stones were pure uric acid, others were pure calcium oxalate and others were mixed.

Of this series of 1,260 cases of renal and ureteral calculi, a history of having taken alkalis in the treatment of peptic ulcer was obtained in only fifteen cases, or 1.2 per cent.

SUMMARY

1. In our present state of knowledge it is generally agreed that the specific cause of renal and ureteral stones is unknown, as is evidenced by the many theories that have been advanced.

2. The difference of 1.8 per cent in the incidence of stone formation between individuals who were given alkalis in the treatment of peptic ulcer and in those who were not is so insignificant as to make it improbable that alkalis used in the treatment of ulcer play a role in stone formation.

3. The incidence of 1.2 per cent of previous ulcer treatment in a series of 1,260 cases of kidney and

ureteral stone is small. Theoretically one might expect the alkalis used in the treatment of peptic ulcer to cause renal stones. The incidence of only 1.2 per cent of treated ulcer cases in a series of 1,260 renal and ureteral calculi, however, does not support this theory.

122 South Michigan Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. HIGGINS, DR. FLOCKS AND
DRS. KRETSCHMER AND BROWN

DR. JOHN MORRISSEY, New York: Urinary stasis and infection have a most important part in the formation of renal calculi. Vitamin A deficiency must be reckoned with as a factor in the general deficiency aspect of the disease. Calcium precipitation in and about the tubules is found both experimentally and clinically in vitamin D poisoning and hypothyroidism. It has also been established that the South African Negro of the Bantu type does not form renal calculi. Nephrostomy, prolonged pelvic drainage and uretostomy, all relatively new procedures, have introduced important new factors into the problem of the patient that outparallel the advance made along purely experimental lines. Continued insistence on the question of urinary stone solution, on methods of prevention and on recurrence and other associated items are very fertile culture mediums for the disturbed mind of the patient with stone. There is nothing more fallacious than the belief that any drug, either directly or indirectly through acidification of the urine, will dissolve a stone in the body. I do not mean to minimize the importance of the fundamental principles set forth by Dr. Higgins or the important observations of these thirty-five cases by Dr. Flocks with calcium stones. I do think, however, that continued insistence on the importance of dietary factors, chemotherapy and food deficiencies from vitamins A to Z all combine to place and retain the patient, whose ailment is 100 per cent a surgical urologic problem, in the hands of those practitioners who would temporize, whose clinical perspective is not surgical, and whose relative ability to handle properly the varied features of a problem of this type are inadequate. Thorough recognition and study of the fundamental principles set before us this morning will enable us of ourselves to evaluate for the patient more thoroughly, intelligently and completely his stone problem in the light of modern scientific urologic research.

DR. ROY J. HOLMES, Miami, Fla.: I feel that the overwhelming majority of recurrent renal calculi are, in reality, false recurrences. When one considers that the incidence of recurrence has been reduced from 50 to 10 per cent during the past twenty years, it seems improbable that such a marked reduction could be accounted for in any other manner than by improved x-ray and surgical management. By this I do not intend to minimize the importance of recent work on true recurrence which has been so well brought out by Dr. Higgins. Urologists have not progressed to the point in management of the kidney that has been operated on to account for such reduction on the basis of control over the etiologic factors. In my series I found that, if the renal pelvis was excluded, 80 per cent of all recurrent calculi were confined to the lower calix. Joly found the proportion six to one. This is of great importance, since it means that either the lower calix is by far the greater stone-bearing area or else it constitutes a stagnant pool well situated to catch and retain small calculi from other portions of the kidney. The predominant picture is that of a moderate sized stone blocking the neck of the lower calix with several sandlike particles in the minor calices. I am willing to admit that, even with the x-ray and various types of suction, I approach the problem of removing every vestige of sand from the lower calix with considerable fear and trembling. Dr. Higgins, in recognition of this point, has spoken favorably of heminephrectomy in selected cases in which there is dilatation of the calix. I not only agree with this point but might add that recently I have resorted to what might be termed a conservative resection of the lower calix. This work has not progressed far enough to justify more than casual mention. I feel, however, that if by partial encirclement of the lower calix with mattress sutures we can remove that comparatively small portion which has proved itself a

habitual menace to the welfare of the entire kidney, we shall have gone far in correcting the problem of false recurrences. The study by Dr. Flocks of ureteral urine taken from each kidney at the same time is very interesting. It is apparent that a small stone in the kidney may, by partly obstructing the outflow of urine, establish a vicious circle in which the higher calcium concentration may serve to overwhelm further the protective colloids and lead to further agglutination of the crystalloids. The value of an intake of large quantities of water in cases of hypercalcemia has been emphasized. This is also the best treatment for combating urea-splitting organisms found in about 50 per cent of such urines.

DR. CHARLES C. HIGGINS, Cleveland: One presumption that has frequently been made in the literature and that has been referred to is the statement that when the patient has been on a diet containing adequate amounts of vitamin A there is no reason to believe that vitamin A deficiency is present. These deductions are fraught with error and I believe that roentgen biophotometer tests should be made in every patient with lithiasis. Dr. Sargent has asked the question: What is a logical routine do you use to prove complete removal of all stones? I believe that as a matter of routine a roentgenogram of exposed kidney should be secured at the time of the operation. This can be done very easily and I believe it is preferable to the use of the fluoroscope. The question has been asked as to whether or not a stone wave is occurring in the United States. In a review of the literature, I have found no evidence that calculous disease is increasing in frequency in this country. It has been noted by von Lichtenberg, Geza Illyes and others that following the World War there was a definite increase in calculous disease in certain parts of Europe. These men have stated that this was probably due to the fact that invading armies, not having adequate commissaries, were required to derive their food from the locality in which they were stationed; therefore the people in these communities were on a definitely deficient diet for extended periods of time. Obviously, other factors are associated with the formation of renal calculus. I have not seen the lesion of the papilla which Dr. Randall has described, although I have studied numerous kidneys which were removed because of calculous disease. Dr. Randall, however, has clearly shown the frequency of its occurrence. The question is asked as to whether this lesion is similar to that described by Dr. John Caulk in 1912. In 1912 Dr. Caulk described a lesion of the papilla on which there was a calcareous deposit which chemically was found to be composed of calcium phosphate, and later in 1926 Macgowan described a similar lesion.

DR. RALPH C. BROWN, Chicago: It is a satisfaction to an internist to discover that the urologists are about as much in the dark as to the etiology of kidney stone as internists are regarding the fundamental causes of peptic ulcer. There has been a fairly well defined idea that a marked increase in crystalloids in the urine predisposes to stone formation and internists who have occasion to treat many peptic ulcers have been subjected to a good deal of criticism from time to time because of the considerable amounts of alkaline substances used in ulcer treatment. As a matter of fact, we have never had precise information as to what happens with respect to calculus formation in individuals so treated. It was for the purpose of securing such information that Dr. Kretschmer and I undertook this study. On careful questioning of a large number of individuals who had been on ulcer management for from three or six months, some of them longer, it was interesting to find that the incidence of kidney stone after ulcer treatment with alkalis was only 1.8 per cent greater than it was before treatment. Even this small figure would probably vanish if one gave value to such a modifying factor as the normal probability of occurrence of stone in a large group of people who were replying to a questionnaire all the way from five to twenty years after they had been treated for gastric or duodenal ulcer. Furthermore, when Dr. Kretschmer finds that only 1.2 per cent of his very large series of patients with kidney stone gave a history of having been on peptic ulcer treatment at any time, one is forced to draw the conclusion that the use of alkalis in ulcer management has little or no influence in the causation of kidney

stones. It is interesting to bear in mind that there is being carried on a great public propaganda by magazine and radio advertising under the slogan "Keep Yourself On the Alkaline Side." If the use of alkalis really has much to do with this matter of stone formation, it would seem that during the next few years urologists should be called on to deal with a tremendous increase in the number of cases of renal calculus.

THE USE OF PLACENTAL BLOOD FOR TRANSFUSION

FRANK E. BARTON, M.D.

AND

THOMAS M. HEARNE, M.D.

BOSTON

For the past two years the medical profession has been extremely interested in blood banks. The casual reader would be led to believe that this work had been only recently developed. A carefully prepared bibliography, however, shows that the subject of blood banks was first described in 1918 by Oswald H. Robertson,¹ then of the United States Army. The experimental basis for his work was originated by Rous and Turner,² affiliated with the Rockefeller Institute for Medical Research. Dr. Robertson's¹ original article advocated the use of a preserving fluid consisting of 5.4 per cent dextrose combined with 3.8 per cent sodium citrate. In a personal communication dated October 1938, Dr. Robertson still favors this use of sugar and citrate as a preservative.

Rous and Turner² determined the viability of preserved blood cells by means of transfusion of these cells in bulk. Rabbits were used for this purpose. A normal rabbit was bled of a large quantity of blood, up to half its blood volume, causing a marked drop in the hemoglobin percentage and red cell count. Immediately afterward the rabbit was given a transfusion of an amount of preserved rabbit's blood equal to the amount lost in bleeding. The hemoglobin returned promptly to its previous level. The animal showed no ill effects from the procedure, and the hemoglobin and red blood cell count remained normal. This demonstrated that the transfused preserved blood cells were behaving as normal red corpuscles. By this means it was found that rabbit's blood could be kept living for two weeks. Many similar experiments were carried out with the same result.

Further study of the subject is illuminating, as in 1934 Lindenbaum and Stroikova³ reported on the various preserving fluids as studied at the Institute for Blood Transfusions in Moscow. The solutions studied were citrate, a mixture of citrate and physiologic solution of sodium chloride, a solution known as "IPK" and, finally, a dextrose-citrate solution. The Moscow workers concluded that "IPK" solution, sometimes referred to as the Moscow solution, was only slightly more efficacious than citrate and that the dextrose citrate solution was superior. They reported that hemolysis took place in approximately ten days with the citrate solution, in twelve days with "IPK" and in thirty-five days with the dextrose and citrate solution. They considered the dextrose as a nourishing medium

for erythrocytes while the other solutions represented only a culture of red blood corpuscles in their own plasma. Three objections were raised against the use of dextrose:

1. It represents a perfect medium for the growth of microorganisms.
2. Decomposition of dextrose in the preserving fluid leads to the formation of lactic acid.
3. Difficulties are encountered in sterilization.

This subject is not in its infancy; during the same year that the foregoing studies were made Balachovski and Guinsbourg⁴ experimented on the use of preserved blood, using an equal amount of diluent similar to "IPK" and blood, and Ascoli and Vercesi⁵ submitted from the gynecologic clinics of the University of Palermo, Italy, a comprehensive report on the use of placental blood in transfusions. The latter authors were of the opinion that placental blood was more efficacious than common blood and prophesied that cord blood would find a wide application in general hospitals.

In 1936 Novikova and Farberova⁶ wrote a concise and instructive treatise on the use of placental blood from the Institute for Blood Transfusions in Leningrad. The technic described had been in use by these authors since 1933. They noted that placental blood averaged from 90 to 100 per cent hemoglobin and had from 5 to 6 million erythrocytes; that there was a relatively large amount of bilirubin and a low cholesterol and albumin fraction of the blood, while the amount of globulin was increased; that the potassium and calcium contents were relatively large and that the large amount of copper present should form a great advantage over adults' blood. The authors admitted the disadvantage of the small yield from one cord but stated that this could be overcome by the fractional use of two or more and warned that the blood from each cord should be transfused separately to prevent reaction.

During the same year Stavskaya⁷ reported on the use of placental and retroplacental blood. He concluded that:

Placental blood is indicated chiefly when not substitution but stimulation therapy is required, for example: (1) in anemias, because the placental blood contains a large amount of hemoglobin, erythrocytes and bilirubin; the bone marrow is stimulated and plastic material for regeneration of erythrocytes furnished; (2) in hemorrhagic diathesis; in these cases placental blood is valuable because of its increased coagulability; (3) in shock.

Keller and Limpach⁸ in 1938 reported on the use of placental blood from the Strasbourg Lying-in Hospital. Their observations were similar to those of other workers mentioned previously. However, they did mention the beneficial results of the use of the blood against ray sickness after ultrapenetrating roentgen therapy.

The pioneer work in the use of placental blood for transfusions on this continent was done by Drs. Goodall and Anderson of Montreal and their co-workers.⁹ Dr.

Goodall not only brought to our attention the availability of placental blood for transfusions but also contributed a workable technic for the collection of the blood and its preservation. Dr. Goodall is an advocate of the "IPK" solution as proposed by the Moscow Institute of Hematology.

In March 1938 our hospital instituted a placental blood bank. The technic adopted was that set forth by Dr. Goodall.⁹ Modifications of this technic have been made and laboratory studies carried out. We have attempted to answer the following questions: 1. Is the blood clean? 2. What is the best preservative? 3. What is the life of the blood? 4. Is the blood of use clinically and if so under what conditions?

Our attempt to modify Dr. Goodall's technic has been (1) to establish a more aseptic technic of collection, (2) to reduce the percentage of reactions and (3) to simplify the securing of a sample of blood for direct typing.

Fig. 1.—Average degree of hemolysis of ten placental blood banks with "IPK" and dextrose.

PROBLEMS

1. *Is the Blood Clean?*—With every collection of blood that is to be preserved for transfusion there has been an inoculation of sterile broth. The broth is incubated for from five to seven days. A culture is then transplanted on plates to determine what organism, if any, is present. The technic of securing the blood has improved to such an extent that at present it is only in a rare case that it needs to be discarded. We contemplate omitting the incubation of the plates and relying entirely on the examination of the broth, the flask corresponding to the culture that is turbid being discarded. Dr. Goodall⁹ is of the opinion that any infection becomes so attenuated that it is innocuous after standing in the ice chest. Our technic, however, is extremely simple and we would rather be on the safe side.

2. *What Is the Best Preservative?*—When we began our study of placental blood we used the "IPK" solution advocated by Dr. Goodall.⁹ Specimens were collected in flasks and sent to the laboratory. These

flasks were unopened until hemolysis was observed. The average length of time before hemolysis set in was 14.4 days. Hemolysis was completed in these flasks in anywhere from forty-two to ninety-one days. Following the recommendations of Robertson¹ and of Lindenbaum and Stroikova,³ we began using "IPK" and 5 per cent dextrose. In this series the hemolysis did not begin for 22.3 days. This change in preservative increased the availability of the blood by eight days. We recommend the use of this solution. Because of the technical difficulties of the ice chest, there was undue agitation of the flasks, which gave us our figure of 22.3 days. We are confident that a series of blood specimens now being studied will show an even more delayed hemolysis.

3. *The Life of the Blood.*—We have taken blood counts on the day of collection of a specimen submitted. A blood count is repeated on the same specimen on the day when hemolysis is first noticed. When we first began our study we counted the cells every day from the day of collection. We found that this is not practical, as the agitation caused by securing

TABLE 1.—Blood Count Just Previous to and Four Days Following Transfusion

Condition	Red Blood Cells	Hemoglobin, per Cent
Anemia of the newborn.....	3,250,000-3,920,000	73-87
Malnutrition.....	3,100,000-4,100,000	72-80
Vomiting and diarrhea.....	3,700,000-4,300,000	50-63
Postoperative perineal prostatectomy..	2,750,000-2,800,000	50-52
Carcinoma of the colon.....	3,450,000-3,700,000	60-66
Obstructing prostate.....	2,850,000-3,150,000	60-60
Obstructing prostate.....	3,000,000-3,550,000	50-50
Duodenal ulcer.....	3,120,000-3,300,000	63-67

the blood resulted in early hemolysis. We have proved to ourselves that the decrease in cell count between these dates runs from 5,000 to 300,000, but as hemolysis increases the red cell count decreases. To interpret this finding in a practicable sense, flasks are usable until the twenty-second day when the "IPK" and the dextrose solution are used as preservative. At this time it is wise to discard them. However, in necessity these flasks may be used until hemolysis is well progressed; it must be realized of course that their efficacy has decreased in comparison to the amount of hemolysis. Since we discarded all flasks on the twenty-second day, no reactions have occurred during transfusion.

Figure 1 shows diagrammatically the advantage of dextrose and "IPK" as a preservative over "IPK" alone. Not only does hemolysis take place eight days later but blood counts taken of the solution every four days following the onset of hemolysis reveals blood destruction carried on at a slower rate in blood preserved with the combined solution.

This chart represents an average of ten specimens of blood in which "IPK" was used alone as a preservative and ten in which "IPK" and dextrose were used. To interpret the curve, it is necessary to accept 5 million as the average cell count of placental blood. The blood is diluted one half, with preservative leaving 2,500,000 as an initial factor.

4. *Is the Blood of Use Clinically, and If So Under What Conditions?*—We have used the bloods in the following conditions. These are picked at random: malnutrition, secondary anemia, postpartum hemorrhage, cholecystogastrostomy, pyloric obstruction, carcinoma of the sigmoid, duodenal ulcer (gastrectomy), splenic anemia, carcinoma at the head of the pancreas

(jaundice), obstructing prostate, vomiting and diarrhea, erythroblastosis, papilloma of the bladder and carcinoma of the stomach.

We have made sixty-four transfusions, using seventy-eight flasks. This has been accomplished without a serious reaction and no fatalities.

While carrying out this study, we have compared the blood count just previous to transfusion to the blood count four days following transfusion, with the results given in table 1.

TABLE 2.—The Number of Cases and Percentage of Incidence in Each Blood Type of the 120 Cases in Which Both Maternal and Placental Bloods Were Alike

Total		O		A		B		AB	
Num-ber	Per Cent	Num-ber	Per Cent	Num-ber	Per Cent	Num-ber	Per Cent	Num-ber	Per Cent
120	100.0	64	53.3	41	34.2	11	9.2	4	3.3

The interpretation of our results would lead us to agree with Stavskaya's⁷ report that the blood is of more use in stimulation therapy than in substitution. We are studying the effect of placental blood on the reticulocyte count but our data at present are not sufficient to warrant a conclusion.

TECHNIC

1. *Establish a More Aseptic Technic of Collection.*—To prevent contamination, Dr. Goodall⁹ suggested that a sterile towel with a hole in the center be applied

Fig. 2.—Table prepared for the collection of placental blood.

to the surgeon's gown. We have modified this technic by using large sterile cloth mittens that are slipped on over the surgeon's gloves and wrists, thereby preventing contamination when handling the cord.

2. *Reduce the Percentage of Reactions.*—Since 1934 all the intravenous solutions of dextrose and sodium chloride have been manufactured in our hospital under the supervision of the intravenous service.

Agreeing with Dr. Florence Seibert¹⁰ that pyrogens are the cause of most of the reactions when intravenous fluids are used, and realizing that pyrogens multiply when exposed to the air, we have preserved our blood and its diluting fluid in air-tight flasks, using stazon

Fig. 3.—Use of the sterile mittens in collecting placental blood.

rubber stoppers instead of the familiar gauze stoppers. Reactions are also avoided if the blood is used for transfusion before hemolysis takes place. Our percentage of transfusion reactions is 4.6. This statement may be modified to the extent that since the establishment of the following technic no reactions have occurred: (1) fractional transfusions of more than one flask, (2) the use of blood before the twenty-second day and (3) the use of air-tight containers.

3. *Simplifying the Securing of a Sample of Blood for Direct Typing.*—Our experimental work and the work of others show conclusively that any disturbance of the blood while in storage hastens hemolysis. Knowing by the label that a certain flask is of a certain

TABLE 3.—Placental Blood Types in Entire Series

type is not sufficient reason to use that flask for transfusion. A direct typing must be done. If a flask is to be uncorked and a sample obtained with a pipet and found to be incompatible, this flask will hemolyze much sooner than an unopened flask. To make it unnecessary to disturb the blood, a pilot tube is attached to the outside of the flask. This tube contains a specimen of the blood and diluting fluid. Whenever transfusion is contemplated with this flask, a sample of the blood in the tube is removed for direct typing, and if it is found incompatible the blood has not been disturbed.

PLACENTAL AND MATERNAL BLOOD GROUPING

There were 179 cases in which the type of blood in both maternal and placental blood was determined. An analysis of these blood groupings revealed some very interesting data.

10. Seibert, Florence B.: Cause of Many Febrile Reactions Following Intravenous Injections, *Am. J. Physiol.* 71: 621-651 (Feb.) 1925.

In 120 cases, or 67 per cent of the total series, the maternal and placental bloods were of the same type. These 120 cases were further subdivided with the results seen in table 2.

Table 3 shows the relative incidence and percentage of incidence of the various combinations of blood groupings found between the maternal and placental bloods in the entire series of 179 cases.

DESCRIPTION OF TECHNIC

Into a 300 cc. Erlenmeyer flask is placed 12.5 cc. of 50 per cent dextrose solution. To this is added, by weight, 100 cc. of freshly distilled water and the contents of an ampule of citro-seroid¹¹ (25 cc.). The formula of citro-seroid is sodium citrate 5 Gm., sodium chloride 7 Gm., potassium chloride 0.2 Gm., magnesium sulfate 0.04 Gm. and distilled water 1,000 cc. In Lindenbaum and Stroikova's³ original article this formula is referred to as "IPK." A stazon rubber stopper is loosely placed in the neck of the flask. The flask is wrapped and autoclaved. While the contents of the flask are cooling the stopper is inserted in the neck of the flask without the wrapping being removed. This allows the exterior of the flask to remain sterile.

The setup for the collection of the blood includes a flask containing the preservative, a pair of sterile mittens, a funnel, three small test tubes, a bottle of broth, a pipet, two Kelly clamps and a pair of scissors. Following delivery the cord is prepared with iodine, two clamps are applied and the cord is cut between the clamps. The gloved hands are now covered with a pair of sterile mittens. The cord is again sharply cut proximal to the clamp. The end of the cord is pointed downward and the blood collected in the flask through a funnel. The cord may be milked to add to the yield.

As the flow diminishes, blood is collected in two small test tubes, one for a Wassermann test and one for typing. The flask is slightly agitated and 10 cc. of the solution is obtained with a sterile pipet. One half of the content is used to inoculate the broth for a check on contamination; the other half is placed in the third tube and stoppered with a cork stopper. The stoppered test tube containing a mixture of the blood

and solution is attached to the flask with elastic bands. The flask is sealed air tight with a stopper and is not to be reopened until it is to be used for transfusion. The stoppered tube containing the mixture of blood and preservative is known as the pilot tube.

A tag is attached to the flask. On this tag is recorded the name of the patient, the collection number and the date and a space for type, Wassermann reaction and culture report. The flask is then placed on the lower shelf of the refrigerator and kept at a temperature of 38 F. When the blood has been typed and the Wassermann reaction and culture reported negative, these data are placed on the tag and the flask is placed on the shelf above ready for use.

Placental blood may be collected on cesarean section. In these cases there is no chance of contamination. The only variation from the technic used in normal delivery is that the blood collected for the Wassermann test and typing is obtained after the placenta has been delivered.

When transfusion is contemplated, a flask of suitable type is chosen. A sample of the blood in the pilot tube is removed for direct typing. Usually two or three flasks are used for a single transfusion. These flasks are warmed in a bath and a continuous intravenous injection of physiologic solution of sodium chloride is started with an open Kelly bottle. A funnel is placed in the neck of the bottle with a gauze strainer and the contents of one flask are poured into the bottle.

The average yield of a flask is 100 cc. of blood. If a larger amount of blood is desired it may be added in a fractional manner, each flask added separately with a small amount of saline solution intervening between the contents of the flasks. Reactions may follow if contents of two or more flasks are added together.

SUMMARY AND CONCLUSION

From our experience with a placental blood bank which was inaugurated one year ago, we favor dextrose and "IPK" as a preservative. We believe that the percentage of reactions during a transfusion need not be higher than a whole blood transfusion (1) if the blood is used before hemolysis sets in, (2) if the blood is used in a fractional manner and (3) if the containers are kept air tight. We also believe that the blood is safe, economical and efficacious.

ADMINISTRATIVE PROBLEMS IN CON-
NECTION WITH PSITTACOSIS

AND THE IMPORTATION OF AUSTRALIAN PARROTS

J. C. GEIGER, M.D.

A. B. CROWLEY; K. F. MEYER, PH.D.

AND

BERNICE U. EDDIE, M.A.

SAN FRANCISCO

On Jan. 24, 1939, a shipment of fifty-five Australian parrots arrived at the port of San Francisco on the *S. S. Monterey* of the Oceanic Steamship Company. The cargo had been en route from Queensland, Australia, and was intended for exhibition at the Australian Building during the Golden Gate International Exposition. The birds had been obtained from an aviary in Queensland and sixty-two were apparently healthy at the time they left the port of origin. En route seven, mostly King parrots, died. On arrival, the shipment passed through quarantine and was isolated on January 25 contrary to the usual custom at the Australian Pavilion on Treasure Island, which was declared a quarantine area by the United States Public Health Service. The collection of psittacine birds was inspected by the representatives of the United States Public Health Service and the State Department of Agriculture. According to a statement from the representative of the Department of Agriculture, the parrots were "in good health." Notwithstanding three days after arrival ten dead birds (two King parrots [*Alisterus*], three Crimson parrots [*Platyercus*], two cockatoos, one Blue-Cheeked parrot, one Yellow-Mantled parrot and one Blood-Stained cockatoo) were delivered to the George Williams Hooper Foundation, University of California, in accordance with an agreement between the foundation and the Surgeon General, United States Public Health Service, which requires the examination of all dead psittacine birds of importations held in quarantine in the ports of San Pedro and San Francisco. Gross examination of the cadavers revealed general emaciation, moderate to severe hemorrhagic enteritis, and small and pale spleens.

According to subsequent reports, the cages had been held outside the exposition buildings during a rainy night of January 25. The deaths of the nine parrots were attributed to exposure. One bird, found dead on arrival at the port of San Francisco, was included in the delivery made at the laboratory of the Hooper Foundation. Although the usual markings of psittacosis were absent, the organs were injected into mice. Within five days some of the mice died with lesions and microscopic appearances suggestive of psittacosis. Ultimately the virus was demonstrated in nine of the ten birds. On February 1 one dead King parrot and one Blood-Stained cockatoo in an advanced state of decomposition were submitted for examination; the King parrot was emaciated and the enlarged spleen contained the virus of psittacosis. The cause of death of the cockatoo was not determined. On February 13 these observations were reported to the representative of the United States Public Health Service and to the Director of Public Health of San Francisco, who had not been advised of the arrival of the shipment despite the fact that the sanitation of Treasure Island is entirely

under his jurisdiction. Investigation conducted by the San Francisco health department on February 14 disclosed the fact that the parrots were still housed in the Australian Building and that the caretaker considered the quarantine to have expired on February 7 and 8. A check-up by the representative of the San Francisco Department of Public Health revealed that ten birds were missing. On inquiry it was found that the parrots had died, and since it was presumed that the quarantine had been lifted it was not deemed necessary to send the cadavers to any laboratory for examination. In fact, they were buried in the rear of the building. Apparently, the representative of the Australian exhibit had not been advised that the quarantine period invariably extends fifteen days from the date of the last death. Since the last bird had died on February 1 the quarantine would still have been in force on February 14 and the cause of death of the ten birds which succumbed between February 8 and February 14, in all probability to psittacosis, would have been definitely established. At the time the San Francisco health department made the inspection, thirty-one live and one dead King parrots were found. The director of public health of San Francisco requested the immediate removal of the thirty-one parrots to the Angel Island Quarantine Station.

The King parrot found dead on February 13 was examined the next day and presented the lesions of acute psittacosis with extensive necrosis in the liver. On direct examination the exudate covering the pericardium was teeming with elementary bodies. Epidemiologically, this observation amply confirmed previous observations that improper care and exposure activate the latent virus in carriers so frequently present among imported parrots, and acute infections may follow within two to three weeks among the cage mates. The systematic investigations of Burnet¹ on psittacosis in wild Australian parrots in 1935 fail to mention the King parrot (*Alisterus* or *Aprosmictus scapularis*). However, in a more recent report by Burnet² (1939), notable deaths among this species in the wild state in various sections of Australia attest its susceptibility. The experiences with the Australian shipment indicate that the King parrot may have escaped nest infection and thus proved highly susceptible as an adult. The majority of the psittacine birds which died en route belonged to this species. It is reasonable to suspect that they became infected by exposure to the carriers which were in the shipment.

On February 18 a Sulphur-Crested cockatoo was found dead with the gross lesions of pneumonia and enteritis; no virus was found.

A close clinical examination of the remaining thirty-one psittacine birds at Angel Island left the impression with a group of investigators who are familiar with bird diseases that, with the exception of a King parrot, a Blood-Stained cockatoo, a Crimson parrot and a quarrion, the shipment consisted of apparently healthy specimens. However, in the light of past experiences it was fully realized that a fair percentage of the parrots were carriers. Under the ideal conditions of housing in separate cages and uniform temperature there was little likelihood that further deaths would occur. In fact, between February 15 and March 1 the sick birds greatly improved and without a previous history

From the Department of Public Health, San Francisco (Geiger and Crowley) and the Hooper Foundation for Medical Research, University of California (Meyer and Eddie).

2. Burnet, F. M.: Psittacosis in Wild Australian Parrots, M. J. Australia, to be published; Psittacosis in Australia, Sixth Pacific Congress, to be published.

of the shipment or laboratory observations the parrots would doubtless have been released. To permit the exhibit of survivors of a consignment of parrots in which deaths have occurred would, however, have meant courting disaster. Recent experiences in the London zoo amply attest such possibilities. In order to exhaust every means to decide the fate of the shipment and to test some newer diagnostic methods, it was decided to bleed the thirty-one parrots and to subject their blood serum to complement fixation tests with the psittacosis antigen. At the time of the bleeding on March 1 the sick King parrot and one quarrion were killed and the autopsy of both revealed residuals of a psittacosis infection with positive virus. The serum tests yielded a fairly large percentage of positive or suggestive reactions with the psittacosis antigen. The director of public health of San Francisco therefore refused the admission of the shipment to Treasure Island. On March 9 the remaining twenty-nine "healthy parrots" were bled to death and examined. One carrier was found among the corellas (*Kakatoe sanguinea*); one of the quarrions (*Nymphicus hollandicus*) and three of the Sulphur-Crested cockatoos (*Kakatoe galerita*) harbored the psittacosis virus in the enlarged spleens and livers.

COMMENT

The experiences collected in connection with the importation of Australian parrots for exhibition purposes to the American continent amply confirm similar observations previously reported by Levinthal³ in 1935 in England and the studies of Burnet² on native birds collected in the forests of Queensland, Brisbane and Victoria. Since spontaneous psittacosis is widely distributed in the psittacine birds of the Australian archipelago, the risk of reintroducing this malady into aviaries of other countries is great. Ornithologists and inspectors should by this time appreciate the fundamental fact that a clinical examination is utterly useless in judging the state of health of a shipment of parrots. Laboratory examinations by properly qualified and experienced workers are paramount in deciding the admission of a consignment. Such examinations are particularly indicated when the past history of the shipment reports fatalities en route. Unfortunately this type of information is not always available since the shipment is not accompanied by a reliable caretaker. The shipping companies have paid little or no attention to these dangerous consignments. How many passengers have been exposed to the risk of psittacosis by these careless methods of transportation remains unknown. Fortunately, only two persons came in contact with the shipment under discussion. One of the men developed a severe "influenza"; unfortunately, he refused a complement fixation test and consequently the exact nature of his illness presents an unsolved and intriguing problem, since psittacosis is suspected.

From an administrative point of view the handling of the importations left a great deal to be desired. The parrots were not quarantined in an area specially reserved for purposes of this kind but were housed on an exhibition ground at a time when a great many working men could have readily been exposed to the contagion. There was no supervision by the authority entrusted with the maintenance of the quarantine. The collection and the transmission of the dead birds were left to the discretion of a caretaker. It is to his credit that he did the work well and carried out instructions

implicitly. Doubtless he could have contracted psittacosis, and one wonders who would have assumed the responsibility for this illness, since this work was done under the instructions from the federal authorities; but his maintenance was paid by the consignee.

On numerous occasions, attention has been called to the inadequacy of the present quarantine regulations governing the importation of psittacine birds. A period of fourteen days is rarely sufficient to complete the mouse inoculation tests required to prove the presence or absence of the virus in the organs. Present and past experience has shown that acute psittacosis infections frequently develop during the quarantine period or shortly thereafter. Apparently healthy birds are released to the importer or dealer, who in turn promptly sells them to the public. Recently a Panama parrot was returned to a bird shop. Examination disclosed acute psittacosis and the significant fact that the bird had been released from quarantine two weeks before. The present regulations doubtless have protected the United States from widespread outbreaks of the character observed in 1929-1930. However, there is ample evidence to connect the South American and Mexican importations with human infections in California, New York and Oregon. Moreover, it is not unlikely that these shipments may have contributed to the maintenance of psittacosis in bird shops and aviaries of the United States.

In order to be effective, the period of quarantine should be extended to not less than three months, preferably six months. Finally, to derive the full measure of benefit from such a measure, the freedom of the importation from disease should be determined by laboratory tests. For larger parrots the blood serum complement fixation test done by an experienced laboratory may be valuable, since sufficient blood may be readily collected from one of the wing veins. One should, however, weigh judiciously the risk to which the person holding the parrots during the act of bleeding may be exposed. The three psittacosis infections in laboratory personnel reported from Germany by Haagen and Krückeberg⁴ in connection with the organization of control measures amply attest the probable dangers. Since the large and expensive parrots are usually held separately, the cages may be covered with dampened cloths while putting the birds under anesthesia; thus the dispersion of the virus particles adherent to feathers into the air may be reduced to a minimum. In any event, it is advisable to employ, if in any way practicable, those who have had psittacosis or whose serum tests would indicate resistance to the infection.

Shipments of parrotlets or smaller psittacine birds should be treated in a manner similar to those of parrakeets. A sample of from 10 to 20 per cent of the importations should be killed and examined post mortem, and the organs tested for virus by mouse inoculations. Occasionally the virus is weak and repeated passages extending over several weeks may be required to demonstrate it conclusively.

The various procedures just outlined will furnish reasonably dependable information relative to the existence of psittacosis in a consignment. Parrots whose blood serum gives positive complement fixation reactions may or may not be carriers or shedders of the virus. However, there is no reasonable doubt that they have had contact with the psittacosis virus. Psittacine birds with enlarged spleens which are bacteriologically sterile

3. Levinthal, W.: Recent Observations on Psittacosis, *Lancet* 1:1207 (May 25) 1935.

4. Haagen, E., and Krückeberg, V.: Veröffentlich. n. d. Geb. d. Vögelgesundheit, 48: 381, 1937.

on lifeless mediums but yield no virus on mouse passage tests must be considered very suggestive of psittacosis. The shipment may harbor a few carriers which may, under adverse environmental conditions, suffer from relapses and may become dangerous shedders. On the other hand, the absence of anatomic signs coupled with the absence of deaths among the parrots during the prolonged period of observations gives reasonable assurance that active psittacosis is in all probability not present in the importation. While in quarantine, cages with riccbirds (*Padda oryzivora*) should be suitably distributed throughout the rooms or building to test for the contamination of the air with virus which originates from the desiccated excreta of carriers or casks.

The procedures outlined will ultimately confront the health officer with important decisions. It may be necessary to rule that any consignment of parrots or parrakeets must be destroyed if active psittacosis infection is proved or even suspected. Any other procedure, in particular the release of survivors of a group in which deaths have occurred, is incompatible with sound public health practice. Doubtless, the health officer will be confronted with the accusation of ruthless slaughter. In case the shipments consist of parrakeets and parrotlets, he should remain adamant in his decision. On the other hand, as an alternative there may be permitted the periodic blood testing of the large and expensive parrots. Should the tests reveal no new infections over a period of six months, there may be safely transmitted the healthy birds selected from an infected shipment to the importer. The disadvantages of the latter procedure are largely economic, and until means have been found to defray the costs of the tests and those of an extended quarantine it is doubtful whether the bird dealers are prepared to risk importation of tropical birds. Thus the trade in psittacine birds and with it the danger of psittacosis would be enormously reduced. There remains, however, another source of trouble—importations to zoological gardens. It would doubtless be disastrous to prohibit or to curtail the exhibit of psittacine birds in these institutions, which are of great educational value. Fully cognizant of its paramount importance to society, the British Ministry of Health has exempted the consignments of birds of the parrot family for zoological gardens from the regulations which govern the importations to Great Britain. Recent experiences in London⁵ have prompted the Zoological Society to impose a three months quarantine on all newly acquired parrots arriving at the zoological gardens. Precautionary measures have been adopted to protect the personnel supervising the birds while in quarantine and to dispose of the excreta in a sanitary manner. The wearing of rubber gloves, masks and goggles by the attendants looking after the birds is mandatory. Similar steps should be taken in the United States. In fact, if and when the directors of the zoological gardens agree to a three to six months quarantine in approved buildings and under expert supervision, the federal authorities and the local health officer may grant permission to admit psittacine birds to zoological gardens without previous isolation at the port of entry.

Only too often the health official has to meet arguments propounded by representatives of the bird trade that human infections due to exposure of imported

psittacine birds are rare. In this connection it is important to emphasize that the course of the disease is by no means characteristic and is more readily camouflaged by the diagnosis of influenza. Moreover, individuals showing no clinical signs of illness may, none the less, be infected. With the aid of the complement fixation test, these silent infections may be detected. It is doubtless good public health practice to insist on a blood examination of persons who have been exposed to a consignment of diseased parrots.

Evidence produced in this report leaves no doubt that the trade in wild parrots and cockatoos introduces new problems in the control of psittacosis and makes it doubtless expedient to take protective measures.

PELLAGRA IN INFANCY AND CHILDHOOD

TOM D. SPIES, M.D.
CINCINNATI

ALFRED A. WALKER, M.D.
AND

ARTHUR W. WOODS, M.D.
BIRMINGHAM, ALA.

During the past four years we have been studying the natural course of the development of pellagra in an area in which the disease is endemic. The habitual environment and dietary of more than 800 pellagrins in the Nutrition Clinic of the Hillman Hospital, Birmingham, Ala., have been studied. Since it seemed likely that each member of the household would be subjected to the same type of diet as the patient, we extended our studies to include the families of these pellagrins. Accordingly, the nutritional status of each member of the household was ascertained and we found that from one to six persons, including infants and children, showed evidence of pellagra. (It is interesting to note that blacktongue, a canine analogue of pellagra, was found in the dogs fed scraps of the food eaten by these families.) A diagnosis of pellagra was made in 194 children and in six infants, and in each case the diagnosis was confirmed by therapeutic tests. These studies are still in progress, but certain points concerning the manifestations of pellagra in infancy and early childhood have been clarified and form the basis of the present communication.

The children of pellagrous parents have been examined repeatedly, with particular attention directed toward the diet of the mother during pregnancy and lactation and of the child since birth, toward the physical and mental development of the child, and toward the presence or absence of lesions diagnostic of pellagra.

A careful history of the mother often revealed that her diet during pregnancy and lactation was inadequate and that, as a result, the quality of her breast milk was probably poor and the supply often insufficient for the child's needs. The nursing infants, therefore, had to be weaned soon after birth and were given some sort of food, which in many cases was inadequate for their nutritional needs. As they grew older, the majority of these children had poor appetites and usually ate very irregularly. Most of them preferred carbohydrate foods and often refused most of the other foods offered.

5. Troup, A. G.; Adam, Robert, and Bedson, S. T.: Outbreak of Psittacosis in the London Zoological Gardens, *Brit. M. J.* 1: 51 (Jan. 14) 1939.

From the Department of Medicine of the Cincinnati General Hospital, Cincinnati, and the Hillman Hospital, Birmingham, Ala. This investigation was aided by grants to the University of Cincinnati College of Medicine from the Rockefeller Foundation, the John and Mary R. Markle Foundation and Mead Johnson & Co.

The parents seldom attempted to change the food habits of the children, even if a good diet was made available. Analysis of the dietaries of such children shows that in most cases their diets were unbalanced and failed to supply in adequate amounts the foods essential for proper nutrition.

These children usually are underweight and underdeveloped for their age and appear to be undernourished and in ill health. Their parents state that they are irritable, easily frightened and "fretful" and that they cry a great deal. They are listless, tired and apprehensive and they do not manifest the normal interests of childhood. Those of school age find it difficult to concentrate and as a rule have made poor progress in school. Although the children seem too tired to play, they cannot rest. They do not sleep well at night but instead toss about and frequently awake crying. Many of them complain of soreness of the tongue and lips and of burning and pain in the stomach. Usually they suffer from constipation but they may have occasional attacks of diarrhea during the spring and summer months.

The response of infants and children to antipellagria therapy is as dramatic as it is in adults. The administration of nicotinic acid or yeast is followed by rapid improvement, and recent studies have shown that similar improvement follows the administration of monocarboxylic and dicarboxylic acids of pyrazine.¹ The preparation and use of these two chemical compounds have recently been described by one of us.² The total daily dosage of nicotinic acid and of the monocarboxylic and dicarboxylic acids of pyrazine is from 50 to 300 mg. We suggest 10 mg. tablets of nicotinic acid for children up to 6 years of age and 20 mg. tablets from 6 years of age up to puberty. They should be given not less than one hour apart. The monocarboxylic or dicarboxylic acid of pyrazine is dissolved in water and given in divided doses. One and a half ounces (45 Gm.) of brewers' yeast is recommended for children up to 6 years of age and 2 ounces (60 Gm.) for children from 6 years of age up to puberty. The daily dosage of yeast is mixed with milk and given in divided doses. The advantages of using crystalline chemical compounds are the ease of administration and rapidity of action. Yeast, although it is less easily administered, supplies several essential nutrients which these children lack.

Even in the absence of diagnostic lesions of pellagra the disease should be suspected in infants and children of families who have subsisted for long periods of time on an inadequate diet. Frequent examinations often reveal early signs of the disease. The administration of one of the therapeutic agents specific for pellagra in such cases offers a valuable therapeutic test, for these children will show prompt improvement following such therapy if early pellagra is present.

The representative history presented here illustrates the development of pellagra with typical diagnostic lesions early in childhood, and the response to diet and yeast therapy:

CASE 1.—R. J. A., an American white boy aged 3 years, was admitted to the pediatric ward of the Hillman Hospital with characteristic pellagra. The following history was obtained from his mother and father: He was allowed to eat whatever he chose and no attempt was made to have him eat anything he didn't like. His diet usually consisted of rice, honey, syrup, jelly, peanut butter, corn bread, biscuit crust, and occasionally oranges

and prunes. Occasionally he drank a small amount of butter-milk but always refused sweet milk. During the spring of the previous year he had an attack of pellagra which was characterized by a symmetrical erythema over the hands, elbows, knees and around the neck. For the past six months he had occasional diarrhea and vomiting, resulting in a steady loss of weight.

Physical examination showed that the child was undernourished and poorly developed and was unable to walk. There was an area of erythema over the nose and malar surfaces of the cheeks, and large areas of pigmented, desquamating skin over the elbows, dorsum of the wrists, hands, and lower third of the forearms. A smaller area was present on the right side of his neck (collar of Casal).

The child was placed on a high caloric, high vitamin diet, supplemented with 15 Gm. of yeast in iced milk three times a day. Feedings had to be given frequently and in small amounts throughout the day and night. Although on admission he refused to take anything but fluids, he began taking semisolid foods such as scrambled eggs and applesauce on the fourth day in the hospital. His appetite improved remarkably and within ten days he was eating everything in a high caloric diet. The acute lesions over the face and dorsum of the hands healed first and the more chronic ones later. On discharge from the hospital, the pigmented skin on his face, hands and arms was clear and he appeared more alert mentally.

The following case history illustrates pellagra without characteristic lesions in an 11 months old infant. The relationship of the nutritional state of the mother to the child, the necessity for repeated examinations of children of pellagrous parents, the value of the therapeutic test in establishing a diagnosis of the disease and the response to nicotinic acid therapy are demonstrated clearly.

CASE 2.—J. McC., a white boy aged 11 months, was admitted to the pediatric service of the Hillman Hospital because of diarrhea. Various treatments were instituted, including extensive trials on scraped apple, pectin preparations, neoprontosil, paregoric, crystalline vitamin B₁, skimmed milk, acidophilus milk, evaporated milk and mashed banana. There was no improvement in the diarrhea during this period. The following history was given by the parents: The child's mother has always eaten an unbalanced diet, high in carbohydrate and low in protein, minerals and vitamins, despite the fact that a liberal and varied food supply was available until eight years ago. During the past eight years, however, the family income has been irregular and always inadequate for their food needs. The mother and the six other children showed diagnostic evidence of pellagra during 1939 and all were under treatment.

The diet of the mother preceding the birth of this child was inadequate both quantitatively and qualitatively. She seldom had more than one meal a day, which consisted of dried beans, potatoes and occasionally oatmeal with a small amount of evaporated milk. Following the birth of the child her diet remained unchanged, and although she had little milk she nursed him until he was 2 months old. For the first two months of the child's life he received an insufficient amount of breast milk which, because of the mother's deficient diet, was probably of poor quality. At the age of 2 months he had pneumonia. Because he was undernourished, the doctor advised weaning him and prescribed for him a mixture containing 4 ounces (120 cc.) of evaporated milk and the juice of one orange daily. When he was 6 months old the quantity of evaporated milk was increased to 14 ounces (420 cc.). In addition he was given one egg, one serving of green beans or turnip greens and three graham crackers daily. He usually took all the food prescribed, and his diet, since he was 6 months old, had been adequate except in its vitamin D content. He had intermittent diarrhea, however, and failed to gain weight. One week before admission, the diarrhea became severe and since this time he had refused most of his food.

Because of the failure of the child to respond to various accepted methods of therapy for diarrhea and in view of the family history, a diagnosis of pellagra was made even though

1. The yeast, nicotinic acid and monocarboxylic and dicarboxylic acids of pyrazine were furnished by Mead Johnson & Co.

2. Bills, Charles E.; McDonald, Francis G., and Spies, Tom D.: Antipellagria Action of Pyrazine-2,3-Dicarboxylic Acid and Pyrazine Monocarboxylic Acid, *South. M. J.* 32: 793 (Aug.) 1939.

there were no characteristic lesions of the disease. One hundred and twenty-five mg. of nicotinic acid daily was added to his milk for two days. Within twenty-four hours the diarrhea disappeared and there was marked improvement in his general physical condition and appetite. Convalescence was rapid. The diagnosis of infantile pellagra, therefore, was confirmed by therapeutic test.

The following case history illustrates pellagra in early childhood and the response to treatment with monocarboxylic acid of pyrazine:

CASE 3.—B. H., a white boy aged 16 months, was admitted to the nutrition clinic of the Hillman Hospital with severe superficial stomatitis. The following history was given by the parents: The mother had always eaten an unbalanced diet, high in carbohydrates and fat, low in protein, minerals and vitamins. Until the child was 12 months old he received only breast milk. At this time, in addition to breast milk, which he continued to take until he was 14 months old, he began eating potatoes, dried beans, bread and occasionally an orange. He was allowed to eat as much of these foods as he wished and the amount he ate varied from time to time. He gained weight and seemed well until he was 14 months old, at which time he had "colitis" and for two weeks ate but little food, lost weight and became very weak. He was taken to a physician who advised weaning him. Since this time he had 1 pint of buttermilk daily, small amounts of oatmeal, potatoes and crackers, and occasionally an egg. His appetite was poor, he was not well, and he did not gain the 6 pounds (2.7 Kg.) he lost during his illness. Two weeks prior to admission he began refusing to eat and since this time he had only a small amount of oatmeal and buttermilk daily. The day he was admitted he became stuporous and was taken to a physician, who advised admitting him as an acute emergency case.

On admission the child was emaciated and apathetic. His tongue and buccal membranes were covered with superficial grayish ulcerations surrounded by fiery red erythema. No other physical abnormalities were noted. On two successive days the child was given 200 mg. of monocarboxylic acid of pyrazine, which was dissolved in sugar water. Twelve hours after administration the child willingly took food and his apathy disappeared. Many of the ulcerations had begun to heal and the erythema had vanished. One week later his mouth was entirely healed. He was alert mentally and was rapidly regaining his lost weight.

These studies suggest that infants and children who have subsisted on inadequate diets or whose parents have pellagra should be examined frequently for signs of the disease. The prognosis for a child is usually better than it is for an adult, but unless proper therapy is instituted the disease is likely to become increasingly severe as the person grows older until finally the skin, alimentary tract and nervous system become involved. Recovery is rapid and complete if a well balanced diet is given, supplemented, when necessary, with nicotinic acid, yeast or monocarboxylic or dicarboxylic acids of pyrazine.

SUMMARY AND CONCLUSIONS

1. The present study shows that, in an area in which pellagra is endemic, the disease is common among infants and children.

2. Nutritional histories often reveal that the mothers of these children subsisted on inadequate diets during pregnancy and lactation, thus establishing a definite relationship between the diet of the mother and the nutritional state of the infant.

3. Lesions characteristic of the disease are seldom seen in infancy but frequently appear early in childhood. In the absence of typical lesions, the administration of one of the therapeutic agents specific for pellagra offers a valuable therapeutic test in confirming a diagnosis of latent pellagra.

THE ELECTROCARDIOGRAPHIC CHANGES IN ACUTE PERICARDITIS

JOSEPH B. VANDER VEER, M.D.

AND

ROBERT F. NORRIS, M.D.

PHILADELPHIA

Since it is usually a complication of a more easily recognized disease, acute pericarditis in the absence of an obvious pericardial friction rub or of a striking pulsus paradoxus is frequently overlooked. Despite the fact that a definite electrocardiographic pattern almost pathognomonic of acute pericarditis has been described, the value of this method of diagnosis has not been generally recognized. In our limited experience, moreover, several electrocardiograms typical of acute pericarditis have been erroneously attributed to coronary occlusion.

In 1929 Scott, Feil and Katz¹ described transitory elevation of the RT segments in all three leads of the electrocardiogram in a case of hemopericardium and in one of purulent pericarditis. These changes were attributed to cardiac tamponade resulting from increased amounts of pericardial fluid and it was emphasized that this type of electrocardiogram could be differentiated from that of acute myocardial infarction. Since then electrocardiographic changes have been described by others² in cases of pericarditis, hemopericardium and stab wounds of the heart. In most of these reports the electrocardiographic changes were likewise thought to be caused by ischemia of the myocardium resulting from cardiac tamponade. Experimental work on animals, meanwhile, showed that definite and reversible changes in the RS-T segments and T waves could be produced by increasing the intrapericardial pressure.³ No constant electrocardiographic pattern was observed in these various studies, but frequently the changes closely resembled those seen clinically.

In 1937 we⁴ reported a study of fourteen cases of acute pericarditis in which serial electrocardiograms

were taken. In addition to the usual three leads a chest lead, with the apex of the heart and the left leg (lead 5 of Wolferth and Wood⁵), was employed as a routine. A characteristic electrocardiographic pattern was present in five of seven cases of purulent pericarditis and in one case of hemopericardium but in none of six cases of nonpurulent pericarditis. This pattern consisted of elevation of the RT segments in the three limb leads, most marked in lead 2, without the occurrence of significant Q waves. No definite changes were observed in the chest lead. These acute changes persisted for only a few days and in some cases returned to normal despite progression of the disease, with increasing amounts of pericardial fluid and signs of cardiac tamponade. Postmortem examinations were done in ten of the eleven fatal cases. Correlation of the observations

tion to the conventional limb leads. A similar electrocardiographic pattern was found in nearly 50 per cent of the cases of nontuberculous pericarditis and in two of twenty cases of tuberculous pericarditis. Deflections of the RT segments in the chest leads were at times more marked than in the limb leads. They also concluded that the changes of the RT segments were usually caused by subepicardial myocarditis.

Since our previous report we have been using a different precordial lead in the study of cases of pericarditis. This lead is one of those which has recently been recommended for routine use by the American Heart Association and the Cardiac Society of Great Britain and Ireland.⁷ By these organizations, lead 4 F (apex and left leg) was given slight preference to lead 4 R (apex and right arm) as a lead for ordinary use. Lead 4 F is the inverted mirror image of old lead 5 of Wolferth and Wood and, in both of these leads, deviations of the RT segments in acute pericarditis are usually minimal or absent.⁸ In contrast to this, we have found that elevation of these segments in lead 4 R may be even greater than in the limb leads.⁹ To illustrate this point and to reemphasize the importance of the electrocardiogram in the diagnosis of acute pericarditis, the following cases are reported:

REPORT OF CASES

CASE 1.—D. R., a Negro aged 55, admitted to the medical service of Dr. Garfield G. Duncan Nov. 16, 1937, for four days had symptoms typical of lobar pneumonia. On examination, signs of consolidation were elicited over the lower lobe of the left lung. The temperature remained elevated between 101 and 104 F. *Pneumococcus* type II was cultured from both the sputum and the blood. A pleuropericardial friction rub, heard near the apex of the heart November 20, disappeared a few days later. November 28, 45 cc. of cloudy fluid, thought to be removed from the pericardial sac, showed no growth on culture. The pericardial sac was not again tapped. November 30, 120 cc. of cloudy but sterile fluid was withdrawn from the left pleural cavity, but on subsequent occasions small amounts of purulent fluid aspirated from the left pleural cavity gave pure cultures of *pneumococcus* type II. Roentgenograms of the chest at first confirmed the clinical impression of lobar pneumonia in the lower lobe of the left lung and later of a small empyema of the left pleural cavity. The heart shadow was at all times enlarged, but no progressive increase in size was demonstrated. The patient continued to have a high fever and became increasingly dyspneic and cyanotic. The superficial veins of the neck were engorged and the liver became enlarged and tender. Slight peripheral edema was noted. Digitalization had little beneficial effect on the cardiac failure and he died December 11, twenty-five days after admission and twenty-nine days after the onset of the illness.

Of the laboratory data, the electrocardiograms were of especial interest. Repeated electrocardiograms, the first of which was taken November 22, two days after the friction rub was first heard, showed elevation of the RT segments in all leads. A gradual return of these changes to normal began November 26, and by December 10, the day before death, the only abnormalities were diphasic T waves in all leads, which may have been secondary to digitalization (fig. 1).

The anatomic diagnosis was: lobar pneumonia of the lower lobe of the left lung (*pneumococcus* type II); marked fibrinopurulent pericarditis and superficial myocarditis (*pneumococcus* type II); empyema of the left pleural cavity (*pneumococcus* type II); atelectasis of the lower lobe of the left lung; chronic passive congestion of the lungs, liver, spleen and pancreas; hypoplasia of the bone marrow.

9. The exact technic that we employed in taking this lead (4 R) has been recently described in a report by one of us.⁴

Fig. 1 (case 1).—A, record taken two days after a pleuropericardial friction rub was heard, shows an elevation of the RT segments in the three limb leads, greatest in lead 2, and a striking elevation of the RT segments in the precordial lead (apex and right arm). This is the typical pattern of acute pericarditis. B, record taken four days later, shows the changes still present though less marked. C, record taken a few hours before death, shows that RT segments have returned to the normal level and the T waves are diphasic in all leads. Some of this T wave change is probably "digitalis effect," as the patient was receiving full doses of this drug. Postmortem examination revealed 650 cc. of thick pus in the pericardial sac, empyema (both *pneumococcus* type II) and evidence of congestive heart failure.

made on clinical, electrocardiographic and postmortem examinations indicated that there was little or no relation between the amount of pericardial fluid and the electrocardiographic changes. The conclusion was reached that this typical electrocardiographic pattern was associated with superficial myocarditis secondary to inflammation of the epicardium.

Bellet and McMillan⁶ subsequently reported a larger series of cases of acute pericarditis in which the three chest leads of Wolferth and Wood⁵ were used in addi-

5. Wolferth, C. C., and Wood, F. C.: The Electrocardiographic Diagnosis of Coronary Occlusion by the Use of Chest Leads, *Am. J. M. Sc.* 183:30 (Jan.) 1932.
6. Bellet, Samuel, and McMillan, T. M.: Electrocardiographic Patterns in Acute Pericarditis, *Arch. Int. Med.* 61:381 (March) 1938.

At necropsy 650 cc. of thick green pus was found in the pericardial sac and about 400 cc. in the left pleural cavity. Pure cultures of pneumococcus type II were obtained from both these exudates. The thick purulent epicardial exudate was already organizing and there was no cellular infiltration of the underlying muscle. The outer portion of the myocardium of both ventricles, however, was pale staining. Many of the fibers contained droplets of fat and the fibrils were broken. Most of the nuclei were vacuolated. Since the lower lobe of the left lung was evidently compressed by the pleural exudate, the alveolar walls were partially collapsed. Nowhere in sections of the lungs was there any evidence of bronchitis or pneumonia. Large patches of edema and "heart failure" cells, however, were present in the parenchyma. The splenic pulp and the central portions of the lobules of the liver were engorged with blood, and the acini of the pancreas were shrunken. The activity of the bone marrow of a rib and vertebral body was subnormal. The immediate cause of death was thought to be congestive heart failure.

The clinical diagnosis of acute pericarditis secondary to lobar pneumonia was confirmed by the electrocardiogram. The elevation of the RT segments persisted for only a week even though pus continued to be present in the pericardial sac. It is noteworthy that at necropsy most of the 650 cc. of pus in the pericardial cavity was posterior to the heart because of anterior intrapericardial adhesions. The return of the electrocardiogram to normal, the failure to demonstrate a progressive enlargement of the pericardium and the failure to aspirate purulent fluid from what was thought to be the pericardial sac influenced the clinicians against surgical drainage of the pericardium. The fever continued, however, and digitalization had no influence on the signs of heart failure. Since there was no residual pneumonia at necropsy, and the apparent cause of death was cardiac failure, surgical drainage of the pleural and pericardial cavities might have been life saving.

CASE 2.—M. L., a white woman aged 67, admitted to the medical service of Dr. David L. Farley July 17, 1938, had noticed weakness and shortness of breath for a number of months and had been acutely ill with fever and cough, productive of thick yellow sputum, for four or five days. The day before admission, persistent pain in the lower left part of the chest was first experienced. On examination the patient was senile and acutely ill. Herpetic lesions were seen about the lips. She was dyspneic and cyanotic but there was no peripheral edema. The contour of the chest suggested emphysema. Evidence of consolidation was found at the bases of both lungs. The area of cardiac dullness was slightly increased. Although the heart sounds were very faint and a marked pulsus paradoxus was present, a pericardial friction rub was not heard. On fluoroscopy no definite pulsation of the heart was seen and a roentgenogram showed patches of pneumonia in the lower lobes of both lungs. After several unsuccessful attempts to aspirate fluid from the pericardial sac, on July 23, 330 cc. of cloudy fluid was obtained at the apex of the heart in the fifth left intercostal space. Before the fluid was completely removed the pulsus paradoxus disappeared and the cyanosis and dyspnea were lessened. In a smear of this fluid, numerous gram-positive cocci were seen but no growth occurred on culture. Because of the return of cyanosis, dyspnea and pulsus paradoxus on August 1 and 2, 10 cc. and 250 cc. of cloudy fibrinous fluid respectively were removed from the pericardial sac. Air injected at the time of the last paracentesis was shown in a roentgenogram to be in the pericardial cavity. Cultures of both these specimens, however, showed the presence of *Staphylococcus aureus*.

During August further attempts at removing fluid from the pericardial sac were unsuccessful. August 3 and 26, 250 cc. of slightly cloudy but sterile fluid was aspirated from the left pleural cavity. At first the patient's temperature varied between 98 and 101 F., but during August the temperature slowly returned to normal. At the same time the signs of consolidation in the lungs gradually became less marked and the heart sounds

became louder. A pericardial friction rub was never heard. In September, however, although pulsus paradoxus was only infrequently present, the patient became dyspneic and cyanotic. The liver was enlarged and tender, and edema of both legs appeared. Late in September the right leg became increasingly swollen, red and tender. Incision and drainage of the leg because of a suppurative cellulitis were necessary. *Staphylococcus aureus* was cultured from the pus. The patient recovered satisfactorily from this infection and the signs of congestive failure diminished with digitalization. Temporary auricular fibrillation was noted and partial heart block with occasional dropped ventricular beats was observed after the administration of digitalis. Because of senile dementia the patient was transferred to another hospital on October 26.

For much of her stay in the hospital there were a moderate leukocytosis and slight anemia. Small amounts of albumin were present in the urine. At first the blood urea nitrogen

Fig. 2 (case 2).—Bronchopneumonia. A, a routine record taken two days after hospital admission, shows the characteristic pattern of acute pericarditis, which was not suspected clinically. Note the elevation of the RT segments in all leads. These changes persisted for nearly ten days and gradually subsided. Purulent fluid with *Staphylococcus aureus* was obtained on pericardial tap. B shows auricular fibrillation, which was transient, and return of the T waves to the normal level. C, record taken three months later, shows that there is a lowering of the amplitude of the QRS complexes in the limb leads and diphasic T waves. No evidence of pericarditis was present at this time, but digitalis was being given because of mild cardiac failure.

varied between 30 and 53 mg. per hundred cubic centimeters but in September a normal level was present. Other laboratory data were irrelevant. After admission repeated electrocardiograms showed marked elevation of the RT segments in leads 1, 2 and 4. These changes returned to normal July 30. During August the T waves of leads 1, 2 and 4 first became diphasic and then inverted, and a slight lengthening of the PR interval was noted. No further change of the RT segments had occurred when the patient left the hospital (fig. 2).

A routine electrocardiogram was responsible for the discovery of acute pericarditis in this patient, who was acutely ill with bronchopneumonia. Because of the patient's age and the apparent subsidence of a mild pericarditis following aspiration, operation was deemed inadvisable. It was felt that the typical electrocardio-

graphic pattern of pericarditis as well as the clinical condition excluded the possibility of coronary occlusion.

CASE 3.—D. G., a white boy aged 13 years, admitted to the medical service of Dr. David L. Farley June 22, 1938, complained of anorexia and diarrhea. He was known to have had rheumatic heart disease since the age of 6 years and had attended the cardiac clinic of the Pennsylvania Hospital. For two weeks before admission he had fever, loss of appetite and slight diarrhea. On admission, the previous diagnosis of mitral stenosis and insufficiency and aortic insufficiency was confirmed. The systolic blood pressure was 120 and the diastolic 30 mm. of mercury. He appeared feverish and acutely ill. At first the patient's temperature was elevated daily as high as to 103 F. but the fever gradually subsided and he appeared improved. In the hospital he had no diarrhea. During August, however, he became worse and his temperature varied between 99 and 102 F. A pericardial friction rub was first suspected August 11 and by August 13 was marked to the left of the sternum, from the second to the fourth interspace. A pulsus paradoxus was not noted at any time and the venous pressure was not determined. He complained of precordial pain, became dyspneic and had a dry, nonproductive cough. The liver became larger but there was no peripheral edema. The patient was thought to have an acute exacerbation of rheumatic carditis and early congestive heart failure. In spite of the severity of the illness, his family signed his release from the hospital August 19.

Repeated blood counts showed moderate anemia and leukocytosis. The sedimentation rate at all times was much increased. Roentgenograms of the chest showed a progressive increase in the size of the heart, particularly to the left, but fluoroscopically

August 12 elevation of the RT segments in all leads of the electrocardiogram was first noted and was thought to be typical of acute pericarditis (fig. 3).

The acute pericarditis in this case undoubtedly resulted from rheumatic fever. At the time of admission there was no evidence of pericarditis, although

Fig. 3 (case 3).—Active rheumatic heart disease. A, record taken just after admission to the hospital, shows partial heart block (PR interval 0.24 second) but no definite evidence of active rheumatism with fever, dyspnea and precordial pain, shows the typical pattern of acute pericarditis. A loud pericardial friction rub was subsequently present for several days. No digitalis was being given. Note the elevation of the RT segments in all leads, greatest in leads 2 and 4.

cardiac pulsations were definitely visible. An electrocardiogram taken the day after admission showed a partial heart block (PR interval of 0.24 second) but by July 9 this abnormality had disappeared and the PR interval was 0.18 second. On

Fig. 4.—A, electrocardiogram of a patient with a recent posterior myocardial infarction. Note the elevation of the RT segments in leads 2 and 3, greatest in the latter, and the slight depression of the RS-T segments in lead 1. The precordial lead (4 R) shows a considerable depression of the RS-T segments. Note also the definite Q waves in lead 3, which became more prominent as the T waves rapidly became inverted in leads 2 and 3. The T waves in leads 1 and 4 returned quickly to normal. B, record of a patient with a recent anterior myocardial infarction. Definite elevation of the RT segments are present in leads 1 and 2 with beginning inversion of the T waves. Note also the definite Q waves in these leads and that the RT elevation is slightly higher in the first lead. Slight depression of the RT segments is seen in lead 3. Lead 4 shows a relatively deep Q wave and some RT elevation. The presence of definite Q waves in leads 1 and 4, with a slight reciprocal action of the RT segments in leads 1 and 3, makes the diagnosis of myocardial infarction quite definite. C, electrocardiogram of a patient with a combined anterior and posterior infarction. Elevation of the RT segments is seen in all the limb leads, greatest in lead 2. Q waves are present in all leads, however, and there are marked changes in the QRS complex of the chest lead with the loss of the initial positive deflection (R wave). There was subsequently a rapid change in and as record with deep inversion of the T waves in leads 1 and 2 and an increase in the size of the Q waves in these leads. The deep Q waves persisted in the precordial lead and the T waves became sharply inverted. (The precordial lead taken originally in this case was the old lead 5. It has been reprinted by inverting and reversing the negative so that it conforms to the new terminology. This in no way alters the interpretation and makes it comparable to the other records.) Although the changes in the RT segments per se in this record conform to the pattern of acute pericarditis, the development of typical Q waves and the marked changes in the precordial lead easily differentiate it from this condition.

the electrocardiogram showed a temporary partial heart block (delayed PR interval). The electrocardiogram then returned to normal and, following an exacerbation of the infection, the typical clinical and electrocardiographic signs of acute pericarditis were observed.

COMMENT

A definite and characteristic electrocardiographic pattern is found in many cases of acute pericarditis. This typical pattern consists of elevation of the RT segments in the three limb leads and in the chest lead 4 R (apex of heart and right arm) which we have employed. In the case of the limb leads, elevation may be especially marked in lead 2 or in leads 1 and 2 together. The RT segments may also be more strik-

ingly elevated in the chest lead than in any of the limb leads. These changes may be caused by any type of pericarditis but most frequently by acute purulent pericarditis or hemopericardium. The abnormalities of the electrocardiogram are usually found early in the disease, are transient and may persist for only a few days. It is especially important to remember that the electrocardiogram may return almost to normal even though the infection and inflammation of the pericardial sac may be continuing and the pericardial effusion increasing. In contrast to acute pericarditis, most cases of chronic pericarditis show no definite electrocardiographic pattern, and abnormalities are usually limited to nonspecific changes in the T waves.

The most common lesion with which the electrocardiogram of acute pericarditis is confused is that of coronary occlusion. Since the clinical manifestations of precordial pain, fever, pericardial friction rub, leukocytosis and the like may be present in both diseases, the differentiation between them may at times depend largely on the interpretation of the electrocardiogram. In the case of myocardial infarction caused by coronary occlusion, the early transient abnormalities of the electrocardiogram are usually characterized by reciprocal deflections in leads 1 and 3. Thus in anterior infarction the elevated RT segments in lead 1 are usually associated with slight depression of these segments in lead 3, and in posterior infarction the elevation of the RT segments in lead 3 are also associated with depression of these segments in lead 1 (fig. 4 A). In the case of coronary occlusion, furthermore, definite Q waves are often present in leads 1 or 3 (fig. 4 B), but in acute pericarditis significant Q waves are generally absent in all leads except when they have been present before the onset of the pericarditis. Acute myocardial infarction involving both the anterior and the posterior wall of the left ventricle may give an elevation of the RT segment in all leads similar to that seen in acute pericarditis.¹⁰ In these rare instances, however, the presence of Q waves in the limb leads and changes in the precordial lead establish the identity of the lesion (fig. 4 C). The recently described electrocardiographic pattern of acute lateral infarction, moreover, does not in any way resemble that of acute pericarditis.¹¹ Finally, if there is a return toward normal in the electrocardiographic pattern and particularly if the patient survives, it has been our experience that the subsequent tendency for the T waves to become inverted is much less marked in acute pericarditis than in coronary occlusion.

Until recently the abnormal deflections of the RT segments in cases of acute pericarditis and hemopericardium were explained largely on the basis of myocardial ischemia secondary to cardiac tamponade. Increased amounts of pericardial fluid were thought to increase the intrapericardial pressure to such an extent that coronary insufficiency resulted. To corroborate this view there were several experimental studies on animals in which an increase in intrapericardial pressure produced electrocardiographic changes, some of which closely resembled the pattern which had been described clinically.³ These changes were reversible in most instances. Recent clinical studies, however, demonstrate that the typical pattern of acute pericarditis is frequently seen with no increase in the amount of pericardial fluid and that a marked pericardial effusion

may accumulate slowly or rapidly without significant deflections of the RT segments. Postmortem examination in a number of cases has also indicated that the typical changes in the electrocardiogram are associated with and are probably caused by a subepicardial myocarditis. If the inflammation does not involve the myocardium, however, the pericarditis even though purulent may cause little or no change in the electrocardiogram.

Like any laboratory aid, the electrocardiogram is of greatest value when it gives positive evidence. Negative evidence must always be considered with caution. The electrocardiogram in acute pericarditis may return almost to normal within a few days, even though the changes have previously been striking and even though the patient has not improved. We wish to emphasize, however, that a definite electrocardiographic pattern typical of pericarditis has been described and that the importance of the electrocardiogram in the diagnosis of this disease has been established.

SUMMARY

1. The definite and characteristic electrocardiographic pattern seen in many cases of acute pericarditis was found in the three cases here presented.

2. The electrocardiographic pattern of acute pericarditis can be differentiated from that of acute myocardial infarction.

3. In cases of acute pericarditis, the changes in the electrocardiogram are generally caused by subepicardial myocarditis.

4. Lead 4 R (apex and right arm) is more valuable than lead 4 F (apex and left leg) in demonstrating the electrocardiographic changes in acute pericarditis.

5. The electrocardiogram is important in the diagnosis of acute pericarditis.

Clinical Notes, Suggestions and New Instruments

AN UNSUCCESSFUL METHOD OF BIRTH CONTROL

JOHN R. RODGER, M.D., BELLAIRE, MICH.

The physician called on to advise his patients with regard to birth control is constantly on the lookout for some method just as effective as but simpler in technic than the commonly accepted methods of vaginal diaphragm or condom used with an intravaginal jelly.

One such product, marketed now for several years, consists of a jelly which is forcibly blown into the vaginal vault by a special applicator. The jelly itself does not have an unusual formula, consisting of a gum tragacanth base, boric acid, sodium chloride, oxyquinoline sulfate, lactic acid and glycerin. It does not melt at body temperature. This very effective type of applicator "splashes" the jelly into the vicinity of the cervix, and in the advertising material a contrast medium picture shows the external os well plugged by jelly.

The theoretical consideration of such a method nearly convinces one of its simplicity and effectiveness. The product appears even more attractive after one reads photostatic copies of letters from physicians who report using it successfully in their practice, one such report even coming from the head of the obstetric department in a university hospital. However, following is the record of twenty-three patients who used this method—patients in a small town practice where one's birth control failures do not become lost from sight but "come home to roost" on one's own confinement calendar. This series, while neither large nor observed over a long period of time, never-

11. Wood, F. C.; Wolferth, C. C., and Bellet, Samuel: Infarction of the Lateral Wall of the Left Ventricle: Electrocardiographic Characteristics, *Am. Heart J.* 16: 387 (Oct.), 1938.

theless permits certain definite conclusions. These patients were all of average or above average intelligence, all had had the method fully explained to them and, from careful questioning, all apparently followed directions closely.

Of twelve nulliparous patients, ten have thus far successfully used this method over an average time of 10.1 months, the shortest period of observation being six months and the longest eighteen months. In the nulliparous group there were two failures, one after two months and the other after three months. In the parous group were eleven patients. Successful were three, with an average time of observation of ten months. Pregnancies resulted in eight of the eleven. Two became pregnant one month after beginning this method, two more became pregnant in three months; the longest period of protection was eight months and the average for the group was only 4.1 months.

CONCLUSION

Twenty-three patients were studied who used as a birth control method a jelly forcibly sprayed into the vaginal vault with a special applicator. In the group of twelve nulliparous patients two became pregnant; of the eleven parous patients eight became pregnant.

This method of birth control is only fairly reliable for nulliparous women and is markedly unreliable after there has been a pregnancy.

HYPERSENSITIVITY TO SOLUTION OF POSTERIOR PITUITARY

WALTER McMANN, M.D., DANVILLE, VA.

In 1936 I¹ reported a case of profound shock following the administration of solution of posterior pituitary. To this patient, following a spontaneous abortion, solution of posterior pituitary was given in 0.5 cc. doses at half hour intervals for four doses. Approximately a half hour after the last injection the patient was in shock. Later 1 cc. of solution of posterior pituitary was given, which almost immediately put her into a profound and frightening shock condition.

I am here reporting another case of hypersensitivity to solution of posterior pituitary. This is being done to add another case to the all too meager literature and to try to make the physician more cognizant of the bizarre and sometimes dangerous reactions that may follow the administration of a commonly used drug.

REPORT OF CASE

Mrs. F. F., a tertigravida aged 27, was admitted to the hospital May 14, 1939, with a history of having had vague abdominal and sacro-iliac pains at regular intervals for about twelve hours. Two weeks before she had entered the hospital and had remained there twenty-four hours for the same complaint. At that time she was discharged after the uncomfortable condition had been controlled with sedatives. After thirty-six hours of vague abdominal discomfort it was thought that the wiser procedure would be to induce labor. The patient was at term and also, as an added deciding factor, she lived 24 miles from the hospital.

At 6 a. m. 2 ounces (30 cc.) of castor oil was given. At 6:30 she had a bowel action and a hot, high soapsuds enema was given. As this was being expelled (6:40) 2 minims (0.13 cc.) of solution of posterior pituitary was given hypodermically. Ten minutes later the patient had urticarial wheals over the whole body. She was gasping for breath and was nauseated, the tongue, face and legs were swollen, there was marked pallor and she had the sensation of impending death. The blood pressure, which had been 140 systolic, 80 diastolic, was 76 systolic, 50 diastolic. Epinephrine was given immediately and most of the symptoms disappeared in a short time or were markedly lessened. Vaginal examination at 8 o'clock revealed a cervix effaced and one and one-half fingers dilated.

The presenting part, the vertex, was dipping into the pelvis. At this time the membranes were ruptured artificially. She was delivered at 2:28 p. m. by elective low forceps of a normal boy baby weighing 8 $\frac{3}{16}$ pounds (3,686 Gm.). The placenta was expelled three minutes afterward. During labor morphine one-eighth grain (0.008 Gm.), scopolamine $\frac{1}{100}$ grain (0.0006 Gm.) and pentobarbital sodium $7\frac{1}{2}$ grains (0.5 Gm.) were given in divided doses. The labor was not abnormal—just what would be expected from one that had been induced.

The patient had had two previous deliveries, in 1936 and 1938. She had been nauseated for the entire duration of both of these pregnancies. The second one had been complicated by polyhydramnios. The first labor had been short, the second long. After both she had received 1 cc. of solution of posterior pituitary with no untoward results.

During this pregnancy, the third, she had had only the symptoms that a nervous multipara would have. There were no signs of toxemia. The Wassermann reaction was negative. She did have polyhydramnios, however. At no time were there any allergic signs or symptoms, and the past history was negative for any allergic manifestations.

On her third postpartum day, with her permission, 1 minim (0.06 cc.) of solution of posterior pituitary was injected hypodermically. Almost immediately she had the same reaction that she had had before. The urticaria was worse, particularly on the thighs and back, itching was more intolerable, and dyspnea was not quite as marked and the blood pressure did not drop as far. This may have been because we gave epinephrine as soon as we were sure that an anaphylactic reaction was starting. The hands, feet and face were more swollen than at the time of the previous reaction. Epinephrine was repeated three times, morphine one-sixth grain (0.01 Gm.) was given once. In spite of this, twelve hours later she was very uncomfortable. She complained bitterly of abdominal cramps; the uterus seemed to be in tetanic contraction most of the time. The next day her condition was normal, and three weeks later it was still normal.

COMMENT

Because of the constant and universal use of the drug, it seems strange that more cases of hypersensitivity to solution of posterior pituitary have not been reported. Hasson casually mentions that there have been cases previous to his reported one in 1930. De Lee in a personal communication says he has observed the phenomenon and Dieckman, quoted by De Lee, warns against the possibility. Twelve references were found in the literature, most of the cases being similar to the one reported here. Simon, and Pendleton and his associates subjected their patients to scratch tests with different brands of solution of posterior pituitary with positive results, but the exact mechanism of the phenomenon is not definitely known. Simon denies that there is excessive oxytocic action accompanying the reaction, while Pendleton insists that there is. It is interesting to note that in my case the first injection did not cause tumultuous uterine contractions. Three days afterward, however, when 1 minim was given, uterine cramps were very painful. My patient would not permit scratch tests to be made either on her or on her baby.

There have been several series of cases of postpartum shock reported in the recent literature, in some of which the etiologic factors have been unexplained. It would be interesting to know to how many of these patients solution of posterior pituitary had been given. Perhaps many more cases of shock occur from this cause than one suspects. For this reason I should hesitate before giving large doses and particularly repeated doses of solution of posterior pituitary. In cases of postpartum hemorrhage from atonic uteri, ergonovine preparations are probably safer and should be more efficacious. It is suggested that, when solution of posterior pituitary is given, epinephrine 1:1,000 be ready for instant use. If there is a reaction which cannot be controlled by epinephrine, magnesium sulfate might be tried intravenously.

Special Clinical Article

TREATMENT OF PERITONITIS

CLINICAL LECTURE AT ST. LOUIS SESSION

THOMAS G. ORR, M.D.

KANSAS CITY, MO.

From the surgeon's point of view, peritonitis arising from perforations and leakage from intra-abdominal viscera is of chief interest. Since there is no specific therapy for peritonitis, treatment may be divided into procedures for the removal of the source of the infection and supportive measures to aid natural defenses. When the treatment is being planned, an estimate should be made of the pathologic condition, the altered physiologic function and changes in body chemistry, and the methods to be employed should be based on this estimate in each individual case.

Factors in the treatment of acute peritonitis worthy of special consideration may be outlined and discussed under the following headings:

1. Operation and abdominal drainage.
2. Decompression of the distended intestine.
3. Maintenance of the intestinal tone.
4. Use of peristaltic stimulants.
5. Maintenance of water and chemical balance.
6. Food supply.
7. Local application of heat.
8. Antitoxic serum therapy.
9. Chemotherapy.
10. Bed posture.
11. Oxygen therapy.
12. Blood transfusions.

OPERATION AND ABDOMINAL DRAINAGE

In the early stages of a perforated abdominal viscus it is logical to remove the source of the infection or close the leak by operation to prevent general peritoneal contamination. The results of early operation before abdominal distention and intestinal stasis have developed have been satisfactory. After the infection has become generalized and abdominal distention and inhibition of intestinal activity have occurred, operation is probably of little value unless there is a local accumulation of pus. Conservative treatment of general peritonitis, first advocated by Ochsner and now considerably elaborated, is fundamentally sound. Since peritonitis secondary to appendicitis has received the greatest attention, the value of the conservative method of treatment may be based on this type of infection. Unfortunately a unanimity of opinion does not exist among surgeons concerning the operative and nonoperative treatment of peritonitis due to appendicitis. However, if the issue is not clouded by the inclusion of local or early peritonitis and localized abscess, the weight of evidence is in favor of the nonoperative or conservative method of treatment. Mont Reid¹ warns that the total mortality of acute appendicitis may actually be increased unless the entire medical profession learns the clear indications for conservative therapy. It seems obvious that in a discussion of the treatment of general peritonitis only those cases presenting the clinical signs and symptoms of such infection should be segregated for nonoperative

treatment. In cases in which there is abscess formation, resolution may result if judicious restraint is practiced by the surgeon.

The futility of attempting to drain the peritoneal surface is now generally recognized. As early as 1905 Yates² concluded that drainage of the general peritoneal cavity is physically and physiologically impossible. Any operative procedure designed to expose infected areas and place multiple drains in contact with the peritoneum can only do harm. There is a growing belief that complete closure of the abdomen in the presence of diffuse peritonitis is preferable to any type of drainage. Buchbinder and his associates³ observed that abdominal drainage increased the mortality in experimental peritonitis. Clinical reports have also indicated a reduction of mortality in acute peritonitis when the abdomen is closed without drainage.⁴ Since there is no universal agreement concerning drainage of peritoneal infections, definite recommendations applicable to all cases are difficult to make. When localized collections of pus or necrotic material are encountered at operation, drainage is indicated. Massive drainage is never indicated. Drains should not be placed on the assumption that purulent exudate will collect at a certain site and the presence of drains will prevent it. Any drain within the abdominal cavity is soon surrounded by adhesions and acts as a foreign body. The principle of placing drains so that contact with the peritoneal surface is minimal is good physiologic surgery. If drains are used for diffuse peritoneal infections they should be placed near, but not on, the original source of infection and should be removed early. When purulent exudates are found within the abdomen, adequate drainage of the abdominal wall is essential. Much suturing in the presence of infection adds foreign material and closes contaminated areas which predispose to the development of serious wound infection. In severe infections the peritoneum should be sutured and the remainder of the wound packed open or loosely closed with sutures passed through the full thickness of the abdominal wall down to the peritoneum.

Various procedures have been suggested for cleansing the abdominal cavity at operation. This type of treatment should be abandoned. Complete removal of all infection by washing or chemical sterilization of the peritoneum is quite impossible and contrary to known physiologic principles. Careful removal of excessive exudate by suction as part of the operation is in order, but extended efforts to cleanse the peritoneal surfaces disturb the natural protection against infection. As an infection progresses over the peritoneal surface a defensive exudate is elaborated which, when disturbed or removed, increases rather than decreases absorption. The experimental work of David and Sparks⁵ has shown that a well developed plastic peritonitis almost completely prevents the passage of *Bacillus coli* from the peritoneal cavity into the lymphatic or blood streams. This was found true also of the diphtheria toxin. From the normal peritoneum or in the presence of a transudate, both *Bacillus coli* and diphtheria toxin passed freely into the blood and lymph streams.

1. Reid, M. R.: The Appendicitis Problem, *Surgery* 3: 601 (April) 1938.

A careful selection of cases for operation is necessary. The presence or absence of intestinal distention aids much in the decision. When there is no distention, operation is usually successful. When diffuse infection, abdominal distention, rapid pulse and dehydration are present, conservative nonoperative treatment is the choice.

DECOMPRESSION OF THE DISTENDED INTESTINE

Any rational treatment of intestinal distention must be considered from the standpoint of the effect of such distention on the organism. Is distention a part of nature's protective mechanism or is it evidence of an advanced pathologic condition? Certainly the degree of distention with reduction of peristaltic activity must be considered in estimating the condition of the patient. When auscultation of the abdomen reveals intestinal sounds, peristalsis is present in some degree. Audible peristalsis is a more hopeful sign than a completely silent abdomen. As distention develops, the blood supply of the bowel is reduced by intraluminal pressure. Excessive distention causes tissue destruction or gangrene. Absorption from the intestine is diminished as the intestine distends. Toxic products may be absorbed through the peritoneum when the blood supply to the intestinal wall is destroyed. Decompression of the intestine prevents necrosis of tissue from lack of blood supply, prevents peritoneal absorption and aids in maintaining the tone of the intestinal muscle. This treatment is then effective by preventing dangerous complications due to overdistention during the height of the infective process.

Continuous gastric and duodenal nasal suction as described by Wangenstein⁶ is indicated in the treatment of intestinal distention resulting from peritonitis. The problem is not unlike that of intestinal obstruction. Constant suction through an indwelling nasal tube removes not only the liquid content of the bowel but the equally important gas and swallowed air that are always present. As signs of improvement in the patient's condition develop, the indwelling tube may be used for testing the return of function of the stomach and intestine. By clamping the tube for a period of two or three hours and measuring the intake and output of liquid, one can make an estimation of function. If the aspirated liquid is less than the intake, it may be assumed that peristalsis is again active and the tube may be removed. While the tube is in place the patient may be permitted to drink water and other liquids, which will pass freely through the tube. Drinking and chewing gum add much to the patient's comfort by satisfying thirst and keeping the mouth moist.

The Miller-Abbott⁷ double lumen tube is useful in emptying the entire small intestine above an obstruction and is applicable to the treatment of intestinal distention due to peritonitis. After the technic of its use has been mastered, excellent results may be expected with this type of tube drainage.

The principal danger of continuous suction treatment of the stomach and upper part of the intestinal tract is the reduction of essential secretions, especially the chlorides. Ulceration in the stomach and esophagus and infection of the middle ear in babies have been mentioned as complications of the indwelling tube. The advantages of the tube far outweigh its disadvantages, and the latter are mentioned only as a safeguard.

The use of enterostomy as a means of decompressing the distended intestine complicating diffuse peritonitis is somewhat questionable. When decompression is most needed the intestine has usually lost its propulsive power and when such a condition exists only a short segment will be drained by enterostomy. After peristalsis has been restored, drainage of the intestinal content is not needed. When true organic obstruction or adhesive obstruction has developed with active peristalsis, enterostomy may be indicated. Organic occlusion requires surgical release, whereas acute inflammatory adhesions causing obstruction will usually subside after temporary drainage and permit restoration of intestinal function. High jejunostomy is no more efficient than suction drainage and is not indicated in the treatment of peritonitis.

Under the heading of intestinal decompression and drainage may also be considered the use of enemas. Liquids given in quantity by rectum, when the intestine is inactive, are frequently difficult to expel and may increase distention and discomfort. Animal experiments have shown that the solutions usually employed for enemas do not stimulate peristalsis in the small intestine and therefore would not aid in reducing its distention.⁸ When the critical stage of the disease has passed and intestinal function has begun to be restored, small enemas may be given with benefit. The colon tube may be useful in any stage of the disease to aid in removing gas from the colon.

MAINTENANCE OF THE INTESTINAL TONE

To maintain the intestinal tone is to maintain the intestinal circulation. The decompression methods discussed obviously aid in maintaining and restoring intestinal tone. Morphine is known to stimulate rhythmic contractions of the intestinal muscle and raise the muscle tone as evidenced by increased intraluminal pressure.⁹ Morphine may then be given with assurance in the treatment of peritonitis not only to increase the muscle tone but in sufficient quantity to make the patient comfortable, promote rest, relieve anxiety and minimize thirst. Overdosage signals are cyanosis and respirations below 15 per minute. When the patient begins to improve, morphine should be promptly diminished and when peristalsis has been restored it should be discontinued entirely. Since hypertonic sodium chloride solutions stimulate intestinal tone and peristalsis, it is reasonable to believe that by maintaining the blood chlorides at a normal level the tone of the intestinal musculature will be favorably influenced. To prevent overdistention of the bowel with its resulting disturbed circulation and at the same time to avoid disturbance of the efforts of the body to protect itself against infection is the principle of such treatment.

USE OF PERISTALTIC STIMULANTS

In view of the generally accepted opinion concerning the protective mechanism of diminished intestinal activity in peritoneal infections, the use of any stimulant which will produce active peristalsis during the acute stage of the disease may be considered harmful. Some clinical evidence has been presented which seems to negative this point of view. Potter¹⁰ has used doses of 1 cc. of pitressin intramuscularly, beginning at the time of operation and given thereafter every

two to four hours until intestinal tone has been regained. Brown¹¹ has expressed doubt about the protective mechanism of intestinal distention against infection and has recommended peristaltic stimulants at the first sign of toxic intestinal paralysis. Since the value of such stimulants is somewhat controversial, they should be used with discrimination. A fall in blood pressure with evidence of shock after the use of pitressin and prostigmine has been observed. When used, the dosage should be small at first and increased if reaction is not noted. The blood pressure is a valuable guide in controlling the patient's tolerance. Indiscriminate use of peristaltic stimulants in all cases of intestinal distention is bad therapy. Further and more scientific research in the clinical application of these preparations is very desirable.

MAINTENANCE OF WATER AND CHEMICAL BALANCE

Since vomiting and inability to assimilate liquids when given by mouth occur with peritonitis, dehydration and loss of essential secretions of the upper part of the gastrointestinal tract assume great importance. When vomiting is excessive, hypochloremia, disturbed acid-base balance and nitrogen retention may result. These changes can be determined by chemical analysis of the blood, which should be done in all cases of serious illness from peritonitis. After a few days of inability to take food, nutritional disturbances may ensue with lowering of the total blood protein, predisposing to general edema and edema of the lungs.¹²

The disturbance in water and chemical balance is best treated by parenteral administration of sodium chloride and dextrose solutions. Ringer's or Hartman's solution may be used, if preferred, instead of physiologic solution of sodium chloride. Sufficient sodium chloride should be given to maintain the chloride content of the blood at a normal level. The quantity of water and chloride necessary will vary with individual patients. Since the daily liquid intake of the average normal adult patient is from 2 to 3 liters, it is reasonable to assume that the sick patient will require at least similar quantities. Coller and Maddock¹³ have quite accurately estimated that a sick patient showing definite signs of dehydration has lost liquid approximately equal to 6 per cent of his body weight. A patient weighing 60 Kg. would therefore require 3,600 cc. of water to combat existing dehydration. To this should be added in the first twenty-four hours of treatment 2,000 cc. to replace the insensible loss through the skin and lungs during that period, plus 1,500 cc. to make up the normal urine output. The total liquid requirement for the seriously dehydrated patient in the first twenty-four hours would equal the sum of 3,600 cc. plus 2,000 cc. plus 1,500 cc., or 7,100 cc. After the initial dehydration has been corrected, the daily necessary intake of liquid will usually not exceed 3,500 cc. When the water deficiency of any patient is estimated, the quantity lost by vomiting or suction, bleeding, drainage from fistulas, diarrhea and massive exudate must be determined and a like quantity restored to the body. As the patient improves and begins to retain liquid and food taken by mouth, the parenteral intake should be proportionately decreased.

As a practical plan for administering the estimated 3,500 cc. of water required in twenty-four hours, it

is suggested that 2,000 cc. of solution be given by vein in the forenoon and 1,500 cc. by hypodermoclysis in the afternoon and evening. Patients who absorb solutions slowly when given by hypodermoclysis should receive the entire daily quantity by vein. The injection of solution should be discontinued before 11 p. m. so that rest during the night will not be disturbed.

Proctoclysis is a time-honored method of supplying liquid to ill patients and undoubtedly has definite merit in selected cases. However, when given to the patient sick with peritonitis it may increase existing distention and discomfort. It is also frequently difficult to estimate accurately the quantity absorbed by the body, since unknown quantities may be expelled about the intake tube or with bowel movements. Proctoclysis is therefore considered inferior to parenteral methods of administration of liquid, especially during the acute stage of peritonitis with abdominal distention.

It is possible to give a patient too much water and sodium chloride. Clark¹⁴ has called attention to the danger of overburdening a weakened circulatory system by rapidly increasing the blood volume. General edema and edema of the lungs may result with excessive hydration when the solution given contains too much sodium chloride. At the first sign of edema the sodium chloride intake should be reduced or discontinued and the injected solution continued as a 5 per cent dextrose solution. Coller and his associates¹⁵ have determined that for each hundred milligrams per hundred cubic centimeters which the plasma chlorides need to be raised to reach the normal the patient should be given 0.5 Gm. of sodium chloride per kilogram of body weight. If this rule is followed and frequent estimations of the blood chlorides are made, the danger of excessive chloride intake will be reduced to a minimum.

FOOD SUPPLY

To maintain metabolic balance during the destructive activity of disease would approach the ideal in therapy. Since this is not possible, especially in diseases of the gastrointestinal tract which prohibit the normal intake of food, parenteral feeding must be used as a poor substitute. At present dextrose is the food of choice which may be given safely intravenously or hypodermically. It is usually given by vein in a 5 or 10 per cent solution. A 5 per cent solution of dextrose is isotonic and may also be given by injection under the skin. Dextrose is particularly valuable in supplying liver glycogen and stimulating diuresis. Recognition of the importance of liver and kidney damage in many disease conditions has emphasized the therapeutic value of dextrose.

Very recently Mueller¹⁶ has recommended the intravenous administration of a 5 or 10 per cent solution of alcohol in the treatment of peritonitis. The alcohol is added to the dextrose and saline solutions to furnish additional, much needed calories. He estimates that 2 liters of 5 per cent dextrose will supply about 400 calories, and if 100 cc. of alcohol is added nearly twice as many calories are available.

Solutions injected intravenously should be given slowly, usually at a rate not exceeding from 60 to 80 drops a minute. The rate of administration of hypodermoclysis must be governed by the rate of

absorption. Excessive tumefaction of the tissues should be avoided. Discomfort may be minimized by adding 50 cc. of 0.5 per cent procaine hydrochloride solution to each liter of liquid to be injected.

LOCAL APPLICATION OF HEAT

Judging by clinical observations, the application of moist or dry heat to the abdomen is of value in the treatment of peritonitis. Experiments have shown that heat at a temperature usually applied clinically will penetrate the abdominal walls of children and thin adults.¹⁷ Ochsner¹⁸ believes that heat stimulates peristalsis. Patients are often made more comfortable by heat applied to the abdomen. Heat may also favorably influence the blood supply to the peritoneum. The dangers of heat therapy are almost nil if the skin is adequately protected against blistering.

ANTITOXIC SERUM THERAPY

Serums have been used with apparent benefit by some authors.¹⁹ Because of the great variety of organisms which may infect the peritoneum from the gastrointestinal tract, the use of polyvalent serums, antitoxic to all pathogenic bacteria causing peritonitis, would be necessary to estimate the true value of such treatment. To date, the benefit derived from serum therapy has not been sufficiently convincing to warrant its routine use.

CHEMOTHERAPY

The value of specific drug therapy is yet to be determined. Sulfanilamide and the newer allied chemicals have not yet proved their worth in the treatment of peritonitis.

BED POSTURE

The semisitting and Fowler positions increase vital capacity and add to the patient's comfort. What effect such positions have on localizing infection in the lower part of the abdomen is difficult to determine. It is possible that gravity may be a factor in preventing the extension of the infection from the lower to the upper part of the abdomen, especially before distention and plastic exudates limit the spread of liquid infectious material.

OXYGEN THERAPY

A certain degree of anoxemia develops in patients with peritonitis as a result of reduced vital capacity, intestinal distention and toxemia. Oxygen should be given to such patients early in the treatment and not as a last resort after cyanosis has developed and dissolution is imminent. Fine and his associates²⁰ have made the important observation that the administration of high concentrations of oxygen promote the absorption of gas from the distended intestine. The importance of oxygen therapy has been emphasized by Thalheimer,²¹ who has stressed the conclusions of Haldane that mild degrees of anoxemia have serious effects on the nervous system and that moderate or severe degrees may be fatal. Oxygen may be given by nasal tube. If the end of the tube is properly placed in the oropharynx, a flow of 6 liters of oxygen a minute will furnish a 50 to 60 per cent concentration to the patient.

BLOOD TRANSFUSIONS

If the disease is prolonged or if anemia develops, transfusions are indicated. Inability to take protein foods by mouth soon causes nutritional disturbances resulting in a decrease in the total blood proteins which predisposes to edema. Transfusions cannot be given in sufficient quantity to restore the blood protein to normal but may be of definite value as a supporting measure.

COMMENT

Since treatment of acute peritonitis is still somewhat controversial in some of its aspects, positive or unqualified statements concerning methods of therapy would hardly be justifiable. Published mortality rates, which vary from 1.5 to 50 per cent, indicate that there has not been a uniform understanding of the pathology of peritonitis and its complicating disturbances of physiology and chemistry. The impression is gained by reading statistical reports that too much emphasis has been placed on total mortality rates and not enough on the segregation of similar pathologic processes with an accurate estimate of the death rate in each group.

Much of the treatment outlined here is unnecessary in mild types of peritonitis. In the fulminating types of infection any treatment may fail. Uniformity of opinion concerning the treatment of peritonitis cannot develop unless a uniformity of pathologic states is considered by every one studying the subject.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

AIRCO OXYGEN HUMIDIFIER ACCEPTABLE

Manufacturer: Air Reduction Sales Company, 181 Pacific Avenue, Jersey City, N. J.

The Airco Oxygen Humidifier is designed to humidify oxygen administered to patients by the oropharyngeal method. When the oxygen passes through the wash bottle, it contains sufficient water vapor not to dry the mucous membrane of the pharynx or larynx at the point where the catheter rests.

The unit consists of a cylindrical bottle, roughly 6 by 15 cm., with tubes attached to a special inlet and outlet to lead from the oxygen tank to the patient. The inlet tube is incorporated in the cap and extends nearly down to the bottom of the cylinder. There are a number of perforations at the distal end of the tube to allow oxygen to bubble through. In addition to an outlet tube there is also incorporated in the cap a spring valve which serves to limit the amount of pressure which may be built up inside the glass cylinder. On the wall of the bottle are lines designating the upper and lower level to which the bottle should be filled with water.

Airco
Oxygen
Humidifier.

If the container is properly filled to the level indicated, there is no danger of blowing water over into the delivery tube. This holds true with oxygen flows of from 4 to 10 liters per minute. (One rarely, if ever, uses more than 8 to 10 liters per minute with a nasal or oropharyngeal catheter.) If the bottle is filled to the top level, the relative humidity of the oxygen delivered ranges from 35 to 50 per cent, with from 4 to 6 liters of oxygen flow per minute.

The humidifier was tested in a clinic acceptable to the Council and found to function adequately. The relative humidity

of the oxygen delivered is somewhat low, but no injurious clinical effects were observed. No pharyngitis was seen or other irritation attributable to insufficient humidity. The amount of humidity required for nasal or oropharyngeal administration of oxygen is an individual problem with each patient anyway. The unit was used interchangeably with another humidifier of known efficiency and no clinical difference was observed. The volume of water is rather small and must be replenished frequently.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Airco Oxygen Humidifier for inclusion in its list of accepted devices.

LIEBEL-FLARSHEIM IMPROVED SW2-C STANDARD MODEL SHORT WAVE GENERATOR ACCEPTABLE

Manufacturer: The Liebel-Flarsheim Company, 303 West Third Street, Cincinnati.

This unit is similar to the Liebel-Flarsheim SW2-C Model Short Wave Generator previously accepted by the Council (*THE JOURNAL*, Nov. 23, 1935, p. 1682) except that it has been improved to allow for an increase in power output. It is recommended for medical and minor surgical purposes. Applications may be made by inductance cable, treatment drum, cuffs, pads and orificial electrodes, and the unit may be employed to induce fever for hyperpyrexia treatments.

Liebel-Flarsheim Improved SW2-C Standard Model Short Wave Generator.

The unit is supplied in a portable wooden cabinet with separate subcabinet and in this form the net weight is about 76 pounds and the shipping weight is about 110 pounds. It is also supplied optionally in a one-piece all metal cabinet and in this form the net weight is 163 pounds and the shipping weight is 265 pounds.

Two oscillator tubes are utilized in a tuned plate, tuned grid, circuit generating a wavelength of about 22.6 meters. The patient, cable and drum circuits are inductively coupled to the oscillator. A filter is employed in the supply line for the purpose of minimizing line feed-back for possible radio interference. The circuit also incorporates a device which protects the oscillator tubes from overload and gives an audible signal when the unit needs readjustment. An electric fan provides forced-draft ventilation.

The firm submitted engineering data to support its claim for the power output of the machine. This is as follows:

Calorimetric Method.—The temperature rise induced in a given amount of water in a given time indicates an average output of 465 watts on the pad circuit and 470 watts on the cable circuit, with an input of 1,160 watts and 1,175 watts respectively.

Photoelectric Cell Method.—Two 300 watt bulbs were arranged in parallel. Measurement of light indicated an average on the cable circuit of 540 watts output with 1,185 watts input, and on the pad circuit 495 watts output with 1,180 watts input.

Tests were carried out for the Council to substantiate these claims. Three separate calorimetric tests were carried out with the apparatus, and the results showed that the claimed output of 470 watts at an input of 1,160 watts could be obtained readily.

The unit was operated at full load for two hours. The transformer temperature rise was found to be low enough to meet the requirements of the Council.

To provide evidence as to the functioning of the machine in heating the human body, the firm submitted a series of tests performed in a reliable clinic.

Treatments were given for twenty minutes each in accordance with the patient's tolerance. For the coil technic, four turns of the cable were wrapped around the thigh with approximately 1 inch spacing of turkish toweling. Two turns were taken high up on the thigh, then about 4 inches of spacing was allowed for inserting the thermocouples, and two more turns were taken below the incision. When the treatment drum was used it was applied over the thigh, as close to the skin and as nearly over the point where the temperatures were read as the

thermocouples would permit. For the cuff technic, two cuff electrodes with approximately one half inch of felt spacer under each were wrapped around the thigh with about 4 inches spacing between the proximal edges.

A Chapman orificial electrode also was used. This electrode was drilled out so that a thermometer could be passed through

Average Temperatures of Six Observations

	Deep Muscle, Degrees F.		Oral, Degrees F.	
	Initial	Final	Initial	Final
Coil technic	98.6	106.3	98.6	98.9
Treatment drum technic	98.4	105.8	98.5	98.8
Cuff technic	98.0	105.3	98.4	98.8

and be in actual contact with the cervical tissue, giving temperature readings from the cervix and not the interior portion of the electrode. A large short wave pad was used as the

Diagram of circuit.

dispersive electrode and was spaced 2 to 3 inches from the lower part of the abdomen by means of a folded turkish towel. The thermometer was left in position throughout the treatment. The duration of each treatment was thirty minutes.

Average of Six Observations, Orificial Technic

Initial, Degrees F.	Final, Degrees F.
101.5 normal	110.2

Nine other tests were made at another hospital, giving the results shown in the table.

Average of Nine Observations, Orificial Technic

Initial, Degrees F.	Final, Degrees F.
98.6	109.6

In addition, eight fever treatment charts were submitted as evidence of the efficacy of the unit in supplying heat for hyperpyrexia. The Liebel-Flarsheim Fever Cabinet was used.

Average of Eight Observations

Initial, Degrees F.	Time Required to Reach 106 F.
97.9	1 hour 41 minutes

The unit was tried in a clinic acceptable to the Council. It was found to give satisfactory service and to perform in accordance to the claims submitted by the manufacturer.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Liebel-Flarsheim SW2-C Improved Standard Model Short Wave Generator for inclusion in its list of accepted devices.

SATURDAY, OCTOBER 14, 1939

SIGMUND FREUD: 1856-1939

On September 22, in his eighty-third year, Sigmund Freud, founder of psychoanalysis, died in London. Men in the future may evaluate fully his contribution to medicine. No doubt much of his teaching will be modified and some of it will be discarded. Certain, however, is the revolutionary influence he has had on psychiatry. Freud was born in 1856 in Freiberg, a small provincial town of Moravia, then belonging to the Austro-Hungarian Empire, a son of simple Jewish parents. His nationality and his race influenced his career. He became a physician though later confessing that his secret desire had been to become a novelist. He was destined to be a profound student of human nature.

In his medical studies Freud was stimulated far more by Charcot and Bernheim in France than by his Viennese teachers. The Vienna Medical School was dominated by the mechanistic attitude of Virchow's cellular pathology. In the light of that concept the unity of the human being as manifested in the functioning of the highest integrating centers (personality) was lost. Freud began his medical career as a neurologist, with contributions on aphasia and on infantile cerebral palsy. Like many of his contemporaries, he soon became aware of the sterility, ineffectiveness and fundamental inadequacy of current neurologic practice in the care of the neuroses. In a search for more light he went to Charcot, whose fame was then at its peak. Charcot had demonstrated experimentally that ideas can produce bodily symptoms. By hypnotic suggestions he had succeeded in reproducing artificially in his patients hysterical symptoms similar to those of which they complained spontaneously.

From Bernheim's and Liébeault's post-hypnotic experiments in Nancy Freud learned that unconscious psychologic processes may influence overt behavior. Next came the observations of Joseph Breuer in Vienna, with whom Freud collaborated after his return from France. The real discoverer of psychoanalysis was Breuer's famous patient Anna, who began to talk

freely under hypnosis of forgotten experiences. This reminiscing while under hypnosis was not simple remembering. It involved a dramatic display and expression of repressed emotions. This verbal outburst of emotions in hypnosis, which had such a beneficial effect on Anna's hysterical symptoms, Freud and Breuer called "cathartic hypnosis"; Anna herself gave it the name "talking cure."

These two factors, remembering of forgotten traumatic emotional experiences and the expression of pent up emotions, have remained two important therapeutic factors in psychoanalysis. Cathartic hypnosis, however, lacked one important element of modern psychoanalytic technic: insight, the intellectual digestion of the repressed forgotten emotional experiences. Under hypnosis the conscious personality of the patient was entirely eliminated. Freud recognized this defect of hypnotic therapy. He tried to reproduce the procedure without hypnosis and during these attempts discovered the most fundamental dynamic fact of psychology—the fact of repression and resistance. In the waking state patients could not face these repressed emotions which came to the surface in hypnosis. Our resistance toward the recognition of emotions, wishes and tendencies which are painful and in conflict with accepted standards Freud called repression. During patient experimentation between 1895 and 1900 Freud discovered the method of free association by which he was able to circumvent the emotional resistance of patients against facing and recognizing their unconscious motive forces. In free association, conscious control is eliminated. The patient gives free course to his ideas, which drift—now converging toward, now receding from, the pathogenic repressed material. During this procedure, more and more of the unconscious repressed material becomes conscious. The physician's role is not active. His influence on this process of self revelation consists mainly in increasing the patient's courage and confidence to face his real self. Now sexual matters, which had been shunned by physicians and patients but which are nevertheless a significant part of our lives, began to become apparent as determining factors in some psychologic disorders. Challenging the hypocritical attitude of his time, Freud described sexual phenomena objectively. The first rejection with which his views were met was mainly due to the publication of these discoveries.

The aim of psychoanalysis, as Freud conceived it, was not to tell people unpleasant truths about themselves but to cure patients by giving the integrative powers of their rational and conscious personality an opportunity to deal with those psychologic forces which were excluded from their conscious mind. Most important was the discovery that repressions may go back to early childhood, when the infantile ego is too weak to deal with the onslaught of violent emotions. Under certain conditions, when these repressions are too excessive, the repressed impulses find a morbid outlet in

neurotic and psychotic symptoms: irrational fears and ideas, depressions, delusions and the whole gamut of psychopathologic phenomena. Psychoanalytic therapy is based on the principle that the mature conscious ego can deal with repressed emotions which the childish ego cannot tolerate.

Most shocking to contemporary attitudes was the discovery of what Freud called the "family tragedy." Naturally, the first emotional difficulties in which the child becomes involved concern its parents. The typical combination of love and hate which the small child feels toward his parents Freud called the "Oedipus complex." More recently, the application of psychoanalysis to children has become a source of important information about early emotional and intellectual development.

The emotional reactions to the freudian observations and formulations made objective evaluation extremely difficult. They permeated scientific discussions and developed strange accusations. Freud was accused of pansexualism, mysticism, dogmatism and unsound speculation. Moreover, Freud was held responsible for every vagary of his actual disciples and many a pseudoscientist who claimed to speak in his name. He was a pioneer working in an unknown territory—the dynamics of the mind; naturally his first generalizations were somewhat vague groping attempts. Nevertheless many of his observations have already passed the test of scientific scrutiny. The facts of repression, resistance, transference, infantile sexuality and its typical manifestations in family life, the unconscious emotional origin of psychoneurotic and many psychotic symptoms, the principal laws of psychodynamics as observed in such mechanisms as rationalization, projection and overcompensation form the basis of both normal and morbid psychology.

Sigmund Freud was 35 years old when he returned from Paris to Vienna and laid the foundations of psychoanalysis. Failing to be accepted and supported by his colleagues in Vienna, including at last even Breuer, he worked for ten years entirely alone. Gradually a few students began to gather around him. Among these early followers were Karl Abraham, Sandor Ferenczi, Max Eitingon, Karl Jung, Alfred Adler, Wilhelm Stekel, Otto Rank, Hans Sachs, Ernest Jones, and others whose names did not become so well known. Some of these pupils were unwilling to follow completely along the untrodden paths into which Freud was leading them. Chief among these dissenters were Jung, Adler and Rank. Yet already psychoanalysis has become firmly established in psychology, in education and in medicine. The technic of psychoanalytic therapy has become standardized and is taught to psychiatrists in psychoanalytic institutes. A number of well trained psychoanalysts are united in scientific societies. The effects of emotional factors on physiologic and pathologic processes are being studied by adequate methods. Such generalities as worry, fear and

overwork as causes of physical disturbances are being replaced by precise descriptions of the emotional factors. By this pathway Freud's influence on general medicine will be most felt in the future. But his influence on our times cannot be evaluated by restricting attention to the medical implications of his teachings alone. All the scientific fields which deal with man's relation to man and all the social sciences have received a new impetus from his dynamic psychology.

DISTRICT COURT IN TEXAS RULES STATE MAY REQUIRE CITIZEN- SHIP IN LICENSURE OF PHYSICIANS

Citizenship may lawfully be required by the state of Texas of an applicant for a license to practice medicine, as a condition precedent to the issue of a license, in the opinion of the district court of Travis County, Texas, in a case brought by a citizen of Mexico.¹ Such a requirement was held not to deprive an alien of any right guaranteed him by the federal constitution. As far as available records show, this is the first time that a court has been called on to pass directly on this question. Under the provisions of the constitution a state cannot deny to an alien the right to follow a "common occupation" under the same conditions that it imposes on citizens. The practice of medicine, the Texas court observed, is not "a common occupation" but is a profession impressed in many instances with semiofficial duties.

Physicians have duties in connection with many important matters relating to the public welfare: duties in connection with governmental birth, sickness and death records; with the execution of certificates of inability of witnesses, or even of the defendant, to attend trial; with matters relating to communicable diseases and quarantine; with the execution of certificates of freedom from disease, required by law in connection with the issuance of marriage licenses, and with the enforcement of state and federal narcotic laws, and many other duties of similar nature. All these duties are imposed on physicians by the government in the furtherance of policies adopted by the state for the welfare of the people as a whole. A physician who is a citizen will be better able to cooperate with the state in carrying out its policies than a physician of foreign allegiance and training who is unfamiliar with the ideals and institutions of our country.

In epidemics, the court pointed out, the closest cooperation is required between the medical profession and various governmental agencies. The virtual end of epidemics of many diseases, such as cholera and smallpox, has resulted from the close partnership that has been maintained between the practicing physicians and

1. Manuel Garcia-Godoy v. State Board of Medical Examiners (Texas), in the District Court of Travis County, Texas, 53d Judicial District, No. 61938.

administrative agencies of the state and federal governments. For the preservation of gains that have been made and in the furtherance of similar objectives, the court thought that the legislature had a perfect right to declare it to be of utmost importance that the practice of medicine be limited to citizens. Again, in time of war the services of physicians constitute a necessary and most important link in our fighting forces; the court thought that physicians who have not signified a belief in the fundamental ideals of this country would be in a position to exert a subversive influence tending to undermine and destroy those ideals and to thwart the attainment of the objectives for which we might

be fighting. For these and other reasons the court felt that it was within the police power of the state to deny to aliens the right to practice medicine to the end that public health, safety and morals might be furthered and preserved.

The court, incidentally, expressed great difficulty in understanding why Texas had ever permitted examinations for medical licensure to be conducted in any language other than English, believing a thorough knowledge of our language to be of prime importance to a physician if he is fully to understand the information imparted by a patient and if he is adequately to give instructions to that patient.

CITIZENSHIP AS A CONDITION PRECEDENT TO MEDICAL LICENSURE IN THE UNITED STATES¹

Numerous alien physicians, and particularly physicians from Germany and the nations it has taken over, have been coming into the United States during recent years for permanent residence. In some states difficult

Germany and Austria.² During the following fiscal year, which ended June 30 last, immigrant physicians numbered 1,384, of whom 819 came from Germany, which during that year included the area formerly known as Austria. During the fiscal year 1931, immigrant physicians numbered 329, while during the fiscal year 1939, just ended, they numbered 1,384.

Statutes and Regulations Governing License to Practice

Citizenship Required		First Papers Required		Neither Citizenship nor First Papers Required
By Statute	By Regulation of Medical Examining Board	By Statute	By Regulation of Medical Examining Board	
Arkansas ¹ Delaware ¹ Florida Georgia ² Idaho Louisiana ³ Nebraska New Hampshire ⁴ New Jersey South Dakota Texas Wyoming	Alabama ¹ Iowa ⁵ Kansas Kentucky Michigan Minnesota ⁶ Missouri Montana Nevada North Carolina Oklahoma South Carolina Tennessee Washington West Virginia	Connecticut Illinois ⁷ Massachusetts ⁸ New Mexico New York ⁹ Pennsylvania Rhode Island ¹⁰ Wisconsin ¹¹	Colorado ¹² Maine Maryland ¹² Mississippi North Dakota Ohio Oregon Utah Virginia	Arizona California District of Columbia Indiana Vermont

1. In Alabama and Delaware, citizenship is required of graduates of foreign medical schools.

2. In Georgia, persons who had resided in the state for at least three months prior to March 23, 1939, who were graduates of a medical school approved by the Association of American Medical Colleges or the State Board of Medical Examiners of Georgia, who had practiced in a foreign state or country for at least twenty years and who had filed first citizenship papers may be issued temporary permits valid for six years. If at the end of that period full citizenship is not obtained, no further license may be issued.

3. In Louisiana, temporary permits may be issued to applicants who have taken out first naturalization papers. By board ruling, licentiate must obtain full citizenship within the time limit prescribed by the federal law on penalty of withdrawal of temporary permit.

4. In New Hampshire, citizenship is required of all applicants except citizens of "a Canadian province in which like privilege is granted to citizens of the United States."

5. In Iowa, citizenship is required of graduates of foreign medical schools, except Canadian schools.

6. In Minnesota, citizenship is required of all applicants except citizens of Canada.

7. In Illinois, the law provides that an applicant shall have obtained first citizenship papers "or having made such declaration of intention, has filed a petition for naturalization within thirty days after becoming eligible to do so."

8. In Massachusetts, licentiate must complete naturalization within five years or else the license is revoked.

9. In New York, licentiate must obtain full citizenship in ten years or else his license is revoked.

10. In Rhode Island, by board regulation, licentiate must obtain full citizenship within five years.

11. In Wisconsin, the law provides that an applicant who by reason of his nationality is ineligible to citizenship, who was a graduate of a reputable professional college in the United States prior to June 22, 1933, and who possesses all other qualifications to secure a license, at least one of whose parents is a native of Wisconsin, shall be licensed.

12. In Colorado and Maryland, first citizenship papers are required of graduates of foreign medical schools.

situations have been created. During the eight federal fiscal years immediately preceding June 30, 1938, 3,165 immigrant physicians arrived, of whom 1,221 came from

How and where these 4,549 alien physicians are now located, what they are doing and what their prospects are of establishing themselves in the practice of their profession, if they have not already done so, is not known. Those who have not yet become United States

1. The data in the table and accompanying it, so far as they relate to statutory requirements, have been compiled by the Bureau of Legal Medicine and Legislation from the statutes of the several states. The data relating to regulations promulgated by state boards of medical examiners have been compiled from information supplied the Council on Medical Education and Hospitals of the American Medical Association by the boards of medical examiners of the several states.

2. Immigration of Alien Immigrant Physicians, J. A. M. A. 112:737 (Feb. 25) 1939.

citizens or even taken out first papers are confronted by statutes and regulations which, except in four states and the District of Columbia, will bar them from licenses to practice. The various statutes and regulations in force governing the matter are herein briefly summarized.

Current Comment

PITUITARY EXTRACT AND LABOR

Although the use of pituitary extract after delivery and in some instances during the final stage of labor has become almost a routine procedure, the questions relating to its indications or possible harmfulness have not yet been settled. Recent reports serve to reopen this important problem. Williams¹ studied fifty normal primiparas given solution of posterior pituitary immediately after the birth of the child and fifty controls treated in exactly the same manner except for the pituitary. Curiously the incidence of postpartum hemorrhage was more than doubled in the pituitary extract series, although the number of patients was too small to warrant definite conclusions on the etiologic role of the drug. There was an average reduction of about five minutes in duration of the third stage of labor for the pituitary group. One contraction ring was encountered, but whether this was due to uterine manipulations or pituitary extract could not be stated. Percival² observed the effects of the intramuscular injection of 5 units of solution of posterior pituitary immediately after the birth of the child in sixty-nine cases of labor. During the same period seventy-four control cases were observed and recorded under similar conditions. He also emphasized that the number of cases studied was too small for the results to carry conviction. As far as the investigation has gone, the intramuscular injection of 5 units of solution of posterior pituitary directly after the birth of the child showed that the duration of the third stage was not appreciably affected, the average loss of blood was less, the incidence of postpartum hemorrhage was less and also there was no tendency for the chorion to be retained; there was no tendency for a contraction ring to form and there was no case of pituitary shock. Clayton³ found, however, that the average duration of the third stage was slightly shorter in cases in which pituitary was given, that the incidence of postpartum hemorrhage of more than 20 ounces (600 cc.) was not reduced and that there is danger of hour glass spasm of the uterus with the ensuing risk of manual removal of the placenta. The definitely uncertain results of the administration of solution of posterior pituitary as obtained by these observers indicate the need for reviewing the entire question of its routine administration. If pituitary extract can be demonstrated to be without the desired effect and even harmful, it should certainly be omitted as a routine procedure in spite of its present wide acceptance and use.

CALIFORNIA

Lectures on Family Relations.—A series of lectures on family relations is being offered at the University of California in Wheeler Auditorium, Berkeley, Tuesday afternoons at 4 o'clock. The lectures are designed among other things, to clarify personal and emotional factors associated with sex and human relations, to survey objectively a demonstrable situation regarding sex and society and to consider means of applying this knowledge to individual and social welfare. Chauncey D. Leake, Ph.D., professor of pharmacology at the university's medical school, will direct the series.

Lectures on Mental Hygiene.—The Mental Hygiene Society of Northern California will present a series of lectures on "Mental Health in Action" at the Mount Zion Auditorium, San Francisco. The speakers will be:

- Dr. Walter L. Treadway, U. S. Public Health Service, San Francisco, October 18, The Poor, the Sick, the Bad.
- Ernest R. Hilgard, Ph.D., Stanford University, October 25, Motives in Industry.
- Dr. Herbert E. Chamberlain, Sacramento, November 1, Mental Hygiene in Daily Life.
- Dr. Jacob Kasanin, San Francisco, November 8, Psychoanalysis and Mental Health.
- Norman Fenton, Ph.D., Stanford University, Calif., November 15, Mental Hygiene and the Teacher.

DISTRICT OF COLUMBIA

University News.—Dr. George W. Thorn, Baltimore, lectured before the naval medical and dental officers on duty in the District and vicinity October 9 on "Supportive Treatment of Infections."

New Department of Psychology and Psychiatry.—The Catholic University of America, Washington, recently created a department of psychology and psychiatry under a grant from the Rockefeller Foundation. The work of the department of psychology, which had been in existence since the founding of the university, has been extended to form the department of psychology and psychiatry. Dr. Thomas V. Moore is head of the department.

Society News.—The Urological Society of the District of Columbia will be addressed by Drs. James T. Priestley, Rochester, Minn., November 8, on "Surgical Procedures in Urology."—At a meeting of the Washington Heart Association November 15 Dr. Tinsley R. Harrison, Nashville, Tenn., will discuss recent advancements in the study of hypertension and renal disease.—Dr. Nolan D. C. Lewis, New York, addressed the section on gastro-enterology of the Medical Society of the District of Columbia October 2 on "The Nervous and Mental Signs of Gastrointestinal Disorders."

ILLINOIS

Postgraduate Instruction in Down State Cities.—A new program of postgraduate education has been adopted by the Illinois State Medical Society which will include several one-day conferences to be held in certain cities of the state. The first conference will be held at the Dunlap Hotel, Jacksonville, November 9, with the following program given by Chicago physicians:

Dr. Robert S. Berghoff, Heart Disease.
Dr. Warren H. Cole, General Surgery.
Dr. Cleveland J. White, Dermatology.
Dr. Philip H. Kreuscher, Orthopedic Surgery.
Dr. Julius H. Hess, Pediatrics.
Howard J. Shaughnessy, Ph.D., Public Health.
Dr. James H. Hutton, Endocrinology.
Dr. Frederick H. Falls, Obstetrics.

Each paper will be followed by discussions. Additional details may be obtained from Dr. Frank Garm Norbury, Jacksonville, or Dr. Berghoff, 30 North Michigan Avenue, Chicago.

Chicago

Seminars on Psychologic Problems.—Dr. Franz Alexander, director, Institute for Psychoanalysis, will conduct the first of a series of five seminars for physicians on "Psychologic Problems in General Medical Practice" October 17. Other lecturers will be:

Dr. Helen Vincent McLean, October 31, Neurotic Gains from Illness.
Dr. Thomas M. French, November 14, Psychologic Aspects of Asthma.
Dr. Leon J. Saul, November 28, Psychologic Aspects of Hypertension.
Dr. Therese Benedek, December 12, Premenstrual Emotional Difficulties.

Clinical Heart Session.—The clinical section of the Chicago Heart Association will hold its first meeting of the season at Michael Reese Hospital October 27. Among the participants will be Dr. Soma Weiss, professor of medicine, Harvard Medical School, Boston. Subsequent meetings of the section will be held monthly at one of the heart clinics of the city. Questions should be sent to Dr. Clayton J. Lundy, secretary of the clinical section, Chicago Heart Association, 203 North Wabash Avenue.

Technical Adviser Appointed on Industrial Hygiene.—Dr. Ludwig Teleky, formerly of Düsseldorf, Germany, has been appointed technical adviser to the division of occupational hygiene of the state department of public welfare, where he will be associated with Dr. Milton H. Kronenberg, chief of the division. Dr. Teleky graduated at the University of Vienna in 1896. He has served as honorary secretary of the Austrian Central Organization for Prevention of Tuberculosis and editor of its journal and as medical expert in the Workers Accident Insurance of Vienna and Lower Austria. In 1939 Dr. Teleky was awarded the Devoto prize of the Reale Istituto Lombardo di Scienze and letters in Milano for the best publication in industrial hygiene.

Society News.—At a meeting of the Chicago Laryngological and Otolological Society October 2 the speakers were Drs. Chevalier L. Jackson, Philadelphia, on "Surgical Treatment of Cancer of the Larynx" and Elmer W. Hagens, "Pathology of the Inner Ear in a Case of Deafness from Cerebro-Spinal Meningitis."—The Illinois Psychiatric Society was addressed October 5 by Max K. Horwitz, Ph.D., and Drs. Erich Liebert and George A. Wiltrakis, Elgin, Ill., on "Metabolism of the Brain Before and After Insulin and Metrazol Treatment as Determined by Oxygen and Carbon Dioxide Content of the Blood"; Maxwell Gitelson, "Concerning the Direct Psychotherapy of Children," and Jules H. Masserman, "Use of Phantasy Tests in Differential Psychiatric Diagnosis."—Dr. Ernest A. Pribram discussed "Management of Diabetes Based on Modern Conception of Carbohydrate Metabolism" before the German Medical Society of Chicago October 3.

Rush College to Be a Graduate School.—Plans are under way to establish a center for graduate training at Rush Medical College within the near future. This announcement was made simultaneously with the news that undergraduate work will be discontinued at Rush in 1942, to provide completion of training for the class entering the autumn session in 1940. Undergraduate training will be continued at the Department of Medicine of the University of Chicago, and after 1942 will be offered there exclusively. The board of managers of Presbyterian Hospital, the teaching unit of Rush, has voted that the hospital remain in its present location on the west side of Chicago. According to a release from the school, decision to establish Rush as a center of graduate medical training terminates discussions as to the ultimate status of Rush, which have been carried on intermittently since 1916. In that year the university approved plans for the south side school which was opened in the autumn of 1927. Rush was chartered in 1837 and has been in operation since 1842, merging with the University of Chicago in 1924 after twenty-six years' affiliation.

KANSAS

Cancer Program.—A statewide lay education program on skin cancer will be carried out during 1939-1940 under auspices of the Kansas Federation of Women's Clubs, Women's Field Army of the American Society for the Control of Cancer and the Kansas Medical Society. An effort will be made to present programs in every town in the state with the local county medical society participating.

Society News.—The Shawnee County Medical Society was addressed in Topeka October 2 by Dr. Paul C. Colonna, Oklahoma City, on "Diagnosis and Treatment of Acute Hematogenous Osteomyelitis."—At a meeting of the Golden Belt Medical Society in McPherson October 12, the speakers were Drs. Letteer G. H. Lewis, McPherson, on "Vitamin K in Relation to Biliary Tract Disease"; Murray C. Eddy, Hays, "Management of Gallbladder and Biliary Tract Disease from the Standpoint of the Surgeon"; Cecil D. Snyder, Winfield City, "Gastric Surgery," and Francis A. Carmichael Jr., Kansas City, "Low Back Pain from the Standpoint of the Neurosurgeon."

MAINE

Annual Fall Clinic.—The Maine Medical Association will hold its annual fall clinical session at Waterville October 25-26. Meetings will be held at the Sisters, Thayer and Elm City hospitals. Wednesday evening there will be a panel discussion on modern anesthesia with the following speakers: Drs. Frederick T. Hill, Waterville, chairman; Howard M. Clute, Marion Fletcher Eades and Sidney C. Wiggins, New York. Gilbert Clapperton, Lewiston, and Paluel J. Flagg, Boston. The session Thursday evening will be the regular meeting of the Kennebec County Medical Society, with Dr. Elliott C. Joslin, Boston, discussing diabetes.

MICHIGAN

Society News.—Dr. Lawrence W. Smith, Philadelphia, discussed "Temperature Factors in Cancer and Embryo Cell Growths" before the Wayne County Medical Society October 9. Dr. Russell L. Haden, Cleveland, will speak October 16 on "The Etiology and Diagnosis of Leukemia."

Neurologic Society Changes Name.—At its first annual meeting in Rochester September 28, the Detroit Society of Neurology and Psychiatry officially changed its name to the Michigan Society of Neurology and Psychiatry. The speakers at the meeting included Drs. Louis A. Schwartz on "An Analyzed Case of Hypertension" and James Clark Moloney, "Comments on the Unconscious."

Field Consultant in Pediatrics.—Dr. Warren E. Wheeler, Dayton, Ohio, has been appointed to the staff of the bureau of maternal and child health of the state department of health as field consultant in pediatrics. His services will be available to local health departments and medical societies on request. The appointment of Dr. Wheeler is a part of the state society's program of postgraduate education for physicians throughout the state (THE JOURNAL, August 5, p. 517). Dr. Wheeler graduated at Harvard Medical School, Boston, in 1933.

MINNESOTA

Society News.—The Minnesota Academy of Medicine was addressed in St. Paul October 11 by Dr. Lee W. Barry on the various types of cesarean section.—Dr. James S. Reynolds, Minneapolis, discussed blindness before the Hennepin County Medical Society at its first meeting of the season in Minneapolis October 2.—At a meeting of the Minneapolis Surgical Society October 5 Dr. Arthur R. Metz, Chicago, spoke on "Chronic Duodenal Stasis."—Dr. Jens E. Meulengracht, Copenhagen, discussed "Principles Underlying the Treatment of Hemorrhagic Peptic Ulcer" in a Mayo Foundation lecture in Rochester August 31. Dr. Meulengracht is chief of Bispebjerg Hospital and professor of medicine at the University of Copenhagen.

MISSOURI

New Trachoma Hospital.—The cornerstone of the Missouri Trachoma Hospital, Rolla, was laid recently. Speakers included Dr. Arthur T. McCormack, Louisville, commissioner of health of Kentucky, and Governor Lloyd Stark. The Missouri State Medical Association was represented by Dr. Eldon C. Bohrer, West Plains. The hospital is located west of Rolla on a five acre tract. When completed it will be the largest hospital of its kind in the world.

pleted, the T shaped building will have a capacity of seventy beds with laboratories, equipment for visual training, recreation and assembly room. It will cost \$136,000.

Society News.—At a meeting of the St. Louis Medical Society September 26 the speakers were Drs. Louis L. Turcotte and John Althert Key on "Fractures of the Vertebrae During Metrazol Therapy"; Paul O. Hagaman, "Treatment of Streptococcal Infections," and William B. Kountz, "Treatment of Peripheral Vascular Diseases."—Drs. Alexis F. Hartmann and Henry L. Barnett, St. Louis, discussed sulfanilamide before the Jackson County Medical Society September 26.—Dr. Thomas G. Miller, Philadelphia, will address the Kansas City Academy of Medicine October 20 on "Recent Advances in Gastroenterology."—At a meeting of the Kansas City Southwest Pediatrics Society September 19 the speakers were Drs. Francis A. Carmichael Jr. and Edwin H. Schorer on "Diagnosis of Cerebral Conditions in Childhood" and "The Business Side of Pediatrics" respectively.—Dr. Thomas M. Paul, St. Joseph, discussed "The Physiologic Basis for the Therapeutic Effects of 'Splenic Extract'" before the Buchanan County Medical Society, St. Joseph, October 4.

NEW JERSEY

Society News.—Dr. William Goldring, New York, will address the Academy of Medicine of Northern New Jersey, Newark, October 19 on "Clinical Aspects of Hypertension and Arterial Heart Disease." Dr. John H. Garlock, New York, will address the section on surgery October 24 on "Surgical Treatment of Carcinoma of the Thoracic Esophagus."

Changes in State Board of Health.—Drs. Frederick P. Lee, Paterson, and Walter G. Alexander, Orange, have been appointed members of the state board of health. Robert P. Fischelis, Phar.D., secretary of the state board of pharmacy, has also been appointed a member of the board under a new law increasing the membership to include a registered pharmacist.

NEW YORK

Society News.—Capt. Rollin L. Bauchspies, M. C., U. S. Army, assistant professor of military science and tactics, Syracuse University School of Medicine, addressed the Onondaga County Medical Society, Syracuse, October 3 on "Medical Service of the U. S. Army in the Field."—Drs. Joseph R. Wiseman and David F. Gillette, among others, will address the Syracuse Academy of Medicine October 17 on "Drug Allergy with Specific Reference to Trypsinamide."—Drs. Gordon D. Hoople, Syracuse, and Marguerite P. McCarthy, Solvay, addressed the Allergy Society of Syracuse October 11 on "Bronchoscopy in the Diagnosis and Treatment of Asthma" and "Analysis of Results in Treated Hay Fever Patients at the Allergy Clinic" respectively.—Dr. Norman H. Jolliffe, New York, addressed the Medical Society of the County of Nassau, Garden City, September 26 on "Recent Advances in Vitamin Therapy (Vitamin B Complex)."—Dr. Philip L. Forster, Albany, addressed the Medical Society of the County of Albany September 27 on "Fat Embolism."—Dr. John H. Ferguson, Syracuse, addressed the annual joint meeting of the Syracuse Academy of Medicine with the Utica Academy of Medicine at the Teugega Golf Club in Rome September 21 on "Crime Detection and the Doctor."

New York City

First Harvey Lecture.—Dr. Arne W. K. Tiselius, Uppsala University, Uppsala, Sweden, will deliver the first Harvey Society Lecture of the current series at the New York Academy of Medicine October 19 on "Electrophoretic Analysis and the Constitution of Native Fluids."

Medicine in Newspaper Forum Program.—One session of the ninth annual Forum on Current Problems sponsored by the New York *Herald-Tribune*, which will be held at the Waldorf-Astoria October 24-26, will be devoted to "Science on the Side of Civilization." Arthur H. Compton, Ph.D., professor of physics, University of Chicago, will give the keynote address, and the other speakers will be Drs. Perrin H. Long, Baltimore, on the development of sulfanilamide in treatment of disease; Francis Carter Wood, New York, progress in the treatment and control of cancer, and Allan Roy Daboe, Callander, Ont., physician to the Dionne quintuplets, "Better Citizens Through Stronger Children."

The Twelfth Graduate Fortnight.—The twelfth Graduate Fortnight of the New York Academy of Medicine will be held October 23 to November 3. The subject will be "The Endocrine Glands and Their Disorders." There will be round table

conferences at the academy building each morning and clinics at hospitals in the afternoons. Evening sessions will be held at the academy with the following speakers:

- Dr. Herbert M. Evans, Berkeley, Calif., Historical Sketch of the Development of Endocrinology.
- Dr. James B. Collip, Montreal, Can., Physiology of the Anterior Lobe of the Pituitary Gland.
- Dr. Leopold Lichtwitz, New York, Pituitary Hypothalamic Syndromes.
- Dr. Leo M. Davidoff, Brooklyn, Hypopituitarism and Hyperpituitarism.
- Dr. Elmer L. Sevringhaus, Madison, Wis., Therapeutic Application of Female Sex Hormones.
- Dr. David Marine, New York, Physiology and Principal Interrelations of the Thyroid.
- Dr. James H. Means, Boston, Hypothyroidism.
- Dr. Harold Thomas Hyman, New York, Medical Aspects of Hyperthyroidism.
- Dr. Frank H. Lahey, Boston, Surgical Treatment of Hyperthyroidism and Other Diseases of the Thyroid Gland.
- Dr. Walter B. Cannon, Boston, The Adrenal Medulla.
- Dr. Robert F. Loeb, New York, Adrenal Insufficiency.
- Dr. Cyril N. H. Long, New Haven, Conn., The Adrenal Cortex.
- Dr. Bernard S. Oppenheimer, New York, The Cushing Syndrome: Neoplasms of the Adrenal Gland.
- Dr. Hugh H. Young, Baltimore, Overfunction of the Adrenal Cortex.
- Dr. Rollin T. Woodyatt, Chicago, Relation of Diabetes to the Endocrine System.
- Dr. John F. Fulton, New Haven, Conn., The Influence of the Central Nervous System upon Endocrine Activity.
- Dr. William G. MacCallum, Baltimore, Physiology and Pathology of Parathyroids.
- Dr. Henry L. Jaffe, New York, Hyperparathyroidism.
- Philip E. Smith, Ph.D., New York, Physiology of the Ovaries.
- Carl R. Moore, Ph.D., Physiology of Testes and Therapeutic Application of Male Sex Hormones.
- Dr. Robert T. Frank, New York, Puberty, Menstruation and Pregnancy.
- Dr. Ephraim Shorr, New York, Menopause.

Several of the programs for the evening sessions were arranged in cooperation with other medical societies and sections of the academy.

NORTH CAROLINA

Symposium on Diseases of the Lungs.—A three day symposium on diseases of the lungs and thorax will be held at Duke University School of Medicine and Duke Hospital, Durham, October 19-21. The speakers will include:

- Dr. Edward C. Churchill, Boston, Anatomical and Physiological Considerations Involved in the Surgical Treatment of Intrathoracic Lesions.
- Dr. Frederick T. Lord, Boston, Clinical Aspects and Diagnosis of Pulmonary Lesions.
- Dr. Daniel M. Brumfiel, Saranac Lake, N. Y., Pneumoconiosis.
- Dr. Chester A. Stewart, Minneapolis, Evolution of Tuberculosis in Children.
- Dr. Harry A. Bray, Ray Brook, N. Y., Clinical Diagnosis of Early Pulmonary Tuberculosis.
- Dr. Cameron Haight, Ann Arbor, Mich., Surgical Treatment of Pulmonary Tuberculosis.
- Dr. William DeW. Andrus, New York, Mediastinal and Other Thoracic Tumors.
- Dr. Isaac A. Bigger, Richmond, Va., Trauma to the Thorax.
- Dr. Charles R. Austrian, Baltimore, Medical Treatment of Suppurative Diseases of the Lungs.
- Dr. Dickinson W. Richards Jr., New York, Pulmonary Fibrosis and Emphysema: Recent Methods of Diagnosis and Treatment.
- Dr. William F. Rienhoff Jr., Baltimore, Surgical Treatment of Lung Abscess and Bronchiectasis.
- Dr. Stuart W. Harrington, Rochester, Minn., Clinical Manifestations and Surgical Treatment of Diaphragmatic Hernia.
- Dr. Maxwell Finland, Boston, Treatment of Pneumonia.
- Dr. Daniel C. Elkin, Atlanta, Ga., Postoperative Pulmonary Complications.
- Dr. Gabriel Tucker, Philadelphia, Bronchoscopy in the Diagnosis and Treatment of Intrathoracic Disease.

OREGON

Society News.—Dr. Conrad A. Loehner, Salem, addressed the Lane County Medical Society, Cottage Grove, September 17 on "Barbiturates and Hypnotics."—Dr. Peter H. Rozendal, Klamath Falls, was elected president of the state association of city and county health officers at the annual meeting in Portland September 1-2. Drs. David R. Rich, La Grande, and Walter H. MacDougall, Oswego, were elected vice presidents and A. Edward Bostrom, Portland, reelected secretary.

Lectures by Dr. Goodpasture.—A series of lectures will be given by Dr. Ernest W. Goodpasture, professor of pathology, Vanderbilt University School of Medicine, Nashville, Tenn., before the Portland Academy of Medicine October 23-25. His subjects will be: "Investigations of Virus Infections and Immunity by Means of Chick Embryo Technique"; "Experimental Bacterial Infections of the Chick Embryo," and "A Consideration of Pathogenesis of Virus and Bacterial Infection, with a Review of Some Virus Diseases."

PENNSYLVANIA

Personal.—Dr. Tom Outland, Sayre, Pa., has been appointed chief surgeon at the Elizabethtown State Hospital for Crippled Children to succeed Dr. James R. Martin, who was appointed James Edwards professor of orthopedic surgery at Jefferson Medical College, Philadelphia (*THE JOURNAL*, August 26, p. 866).—Dr. Theodore Wollak, superintendent of the Torrance State Hospital, Torrance, since 1936, has resigned, it is reported.

Society News.—Dr. Carl J. Wiggers, Cleveland, addressed the Washington County Medical Society, Washington, September 13 on "Physiology in the Practice of Medicine."—At the first fall meeting of the Dauphin County Medical Society, Harrisburg, September 5 the speakers are Drs. Ross H. Childerhose, on "Diagnostic Features and Modern Medical Treatment of Tuberculosis"; William Devitt, Allenwood, "Surgical Treatment of Tuberculosis," and Clarence R. Phillips, "Proper Relationship Between the Lay Organization and the Medical Society."

UTAH

Dr. Freudenberger Named Acting Dean.—Clay B. Freudenberger, Ph.D., professor of anatomy, University of Utah School of Medicine, Salt Lake City, has been appointed acting dean during the absence of Dr. Lyman L. Daines, dean, who has been seriously ill since early in September. News at the university includes the promotion of Dr. Edward I. Hashimoto as assistant professor of anatomy, and the construction of an addition to the medical school building which will increase the facilities by 50 per cent, it is reported.

Hobby Show.—The Salt Lake County Medical Society devoted its meeting September 11 to a hobby show. Under the leadership of Dr. Fuller B. Bailey, the following, among others, displayed their work: Drs. George A. Allen "Live Birds"; Quince B. Coray, "Painting and Charcoal Drawings"; Orlando L. Ross, James Albert Peterson and Edward S. Pomeroy, "Water Colors and Paintings," and Thomas F. Welsh and Ralph C. Pendleton, "Photography."

State Medical Election.—Dr. Alfred C. Callister, Salt Lake City, was chosen president-elect of the Utah State Medical Association at a meeting of the house of delegates at the University of Utah, Salt Lake City, September 4. Other officers include: Drs. Warren O. Christenson, Wellsville, Edwin M. Neher, Salt Lake City, Wilford J. Reichmann, St. George, David E. Ostler, Richfield, vice presidents; David G. Edmunds, Salt Lake City, secretary; Richard P. Middleton, Salt Lake City, treasurer. The next meeting of the state association will be held in Ogden in 1940.

Control of Venereal Disease.—The state department of health has established a bureau of venereal disease control to cooperate with the U. S. Public Health Service in launching a statewide program. Dr. Welby W. Bigelow, Salt Lake City, has been named director of the bureau. Subsidized by federal funds, the state board has adopted a revised system of reporting venereal diseases, and the distribution of free antisyphilitic drugs for indigents and those in low income groups is being made available to regularly licensed physicians. To facilitate reporting as well as free antisyphilitic drug distribution to the private physicians, a system has been set up whereby the physicians will report cases to and receive drugs from their respective district health officers except in Davis and Salt Lake counties. Physicians in these counties will apply respectively to the Davis County health department at Farmington and to the state board of health in Salt Lake City. District health offices are located at Ogden, Cedar City, Price, Provo and Richfield.

GENERAL

Reprints on Infantile Paralysis.—A limited number of bulletins entitled "Care During the Recovery Period in Paralytic Poliomyelitis" are available for distribution by the National Foundation for Infantile Paralysis. No charge will be made. The association is sending copies to members of the American Academy of Orthopedics and the American Orthopedic Association, but interested physicians may have them on request. The brochure is technically designated "Public Health Bulletin No. 242, Revised 1939," U. S. Public Health Service. Requests should be directed to the foundation at 120 Broadway, New York.

Leaflet for Patients Explains Gonorrhea.—The U. S. Public Health Service has issued a leaflet entitled "Gonorrhea the Crippler," designed for physicians to distribute to their patients. The division of venereal diseases prepared it in response to a recommendation by an advisory committee in January 1938, urging the development of a campaign for education of the public and issuance of printed materials. The text

explains the symptoms, points out the fallacies of several common beliefs and gives practical advice, with emphasis on care by a physician. This folder is one of a "dollar-a-hundred" series on venereal disease published by the service. It is available from the Superintendent of Documents, Washington, D. C., at \$1 a hundred copies.

Aero Medical Meeting.—The eleventh annual meeting of the Aero Medical Association of the United States will be held at Hollywood-by-the-Sea, Florida, November 3-5, with headquarters at the Hollywood Beach Hotel. The speakers on the scientific program include:

Dr. Charles L. Leedham, Randolph Field, Tex., The Syndrome of Vasomotor Instability as Seen in Examination of Cadet Applicants for Flying.

Ross A. McFarland, Ph.D., Boston; Dr. Ashton Graybiel, Boston; Dr. Eric Liljencrantz, San Francisco; Col. Arnold D. Tuttle, Chicago. An Analysis of the Physiologic and Psychologic Characteristics of Two Hundred Civil Air Line Pilots.

Lieut. Comdr. William W. Davies Jr., Pensacola, Fla., Some Observations on Cadet Selection.

One feature of the program will be a forum on airline medical problems.

Meeting of Health Officers.—The annual institute of instruction on the practical administrative affairs of the health officer will constitute the yearly session of the International Society of Medical Health Officers in Pittsburgh October 16. The session will be in cooperation with the health officers' section of the American Public Health Association. Among the speakers will be:

Edward Henry Lewinski Corwin, Ph.D., The Problem of Cost Accounting in Public Health.

Dr. Huntington Williams, Baltimore, Practical Staff Policies of a Health Department.

Dr. John L. Rice, New York, Increasing Administrative Efficiency.

Henry F. Vaughan, Dr.P.H., Detroit, Organizing the Health Department for an Epidemic.

Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C., will speak.

New Society of Physical Therapy Physicians.—Dr. Frank H. Ewerhardt, St. Louis, and Dr. William Bierman, New York, were chosen president and president-elect respectively of the Society of Physical Therapy Physicians at its organization and first annual meeting during the annual session of the American Congress of Physical Therapy in New York September 5-8. Other officers include Drs. Frank H. Krusen, Rochester, Minn., and John S. Coulter, Chicago, vice president and secretary-treasurer respectively. Although the group met informally in 1938, the society was not officially organized until the recent meeting. Its membership will be restricted to physicians who devote themselves exclusively to the practice of physical therapy in contradistinction to those of the American Congress of Physical Therapy, which includes all ethical physicians and surgeons who are interested in physical therapy while engaged in general practice. The membership will be limited to 100 bona fide specialists who have devoted at least five years to this specialty and have or are holding teaching and directoral positions in physical therapy in America. Membership will be offered to qualified men by individual invitation, according to the *Archives of Physical Therapy*. The 1940 session will be held separately but during the annual session of the congress at Cleveland.

Government Services

Physicians Wanted for the CCC

Vacancies now exist in the CCC in the eighth corps area wherein the services of physicians can be utilized as civilian employees (physicians) or as contract physicians. Applicants should be graduates of approved medical schools and should address their applications to the surgeon, eighth corps area, Fort Sam Houston, Texas. Consideration will be given to applicants as follows: (1) Medical reserve officers who are eligible for active duty and promotion. They may be placed on duty under classification P-2 at the initial rate of pay of \$2,600 per year. (2) Physicians who are not members of the medical reserve corps can be placed on duty as contract physicians at the initial rate of pay of \$2,600 per year. Applicants must consider themselves physically qualified; if selected, they must report to their first place of assignment at their own expense and if found physically qualified will be appointed at the respective rates. If on being relieved from duty, either at the request of the individual or for the convenience of the government, the return transportation must also be at the expense of the individual.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Sept. 23, 1939.

The London Hospitals in Wartime

The London hospitals have been cleared as far as possible of ordinary patients, mainly with the object of transferring them to places safer from air raids and also to provide accommodations for the large number of casualties expected from this cause. But they still maintain 20 per cent of their accommodations for cases of urgent illness or casualties apart from air raids. One restriction is imposed: only cases from the district in which the hospital is situated are admitted. In normal times the reputation of the hospitals drew patients from far and wide, even from overseas. Operations are now performed in rooms specially equipped on the lower floors. A limited outpatient service is maintained. The enormous medical machine which was created almost overnight for the treatment of casualties from air raids is kept "ticking over." In certain directions medical services are necessarily curtailed. The use of radium is an example. Most of the national stock of radium has been buried at the foot of a 50 foot hole specially drilled for use in war time at one of the hospitals. The radium and its containers are in a steel cylinder, which before being lowered was loaded at the well head by an operator who stood for protection behind a thick block of lead. This valuable stock of radium is thus protected against risk of accident not only with the object of preserving it but as a safeguard against the damage which might be caused if it should be scattered by an explosion. For the present, high voltage roentgen therapy will be used instead of radium treatment wherever possible. The resumption of radium treatment in some parts of the country will soon be considered.

The Use of Poison Gas and Bacteria in War

In the House of Lords, Viscount Halifax, Secretary of State for Foreign Affairs, stated that the British ambassador in Berlin, when asking for his passports from the German government, presented a note inquiring whether the Geneva Gas Protocol of 1925, which prohibits the use of poisonous gas and bacteriologic methods, would be observed by the German government. That government had now replied in the affirmative through the Swiss minister in London as follows: "The German government will observe for the duration of the war the prohibitions which form the subject of the Geneva Protocol. It reserves full liberty of action in the event of the provisions of the protocol being infringed by the enemy." But we are taking no risks in this matter. Not only the fighting forces but every civilian has a gas mask, and in London no one goes any distance without taking his mask. There are special ones for young children and for babies, who could not wear an ordinary mask, a protective helmet in which air is kept circulating by a bellows. Instruction in the use of this helmet is given daily to mothers at the centers for air raid precautions.

The Need for Pharmaceutic Reform

At the British pharmaceutic conference Mr. J. Rutherford Hall referred in his presidential address to the misleading and fraudulent advertisements of nostrums which the government did not control in any way. There was need for some central authority to recognize proper and reliable medicaments. A combination of the British Pharmacopoeia and the United States Pharmacopoeia might be the first stage in securing a Universal Pharmacopoeia. But this did not solve the whole difficulty in settling what were proper and reliable medicaments. New drugs and methods of treatment were being constantly introduced.

Some standing authority was therefore necessary, with power to act and make recognitions and regulations as occasions arose. He had in mind some such body as the Council on Pharmacy and Chemistry of the American Medical Association, which published an approved list of new and nonofficial remedies, the purpose of which was to protect the medical profession and the public against fraud, undesirable secrecy and objectionable advertising in connection with proprietary medicines. Such a body, to be effective, would need legal sanction.

The welter of names and the confused nomenclature of medicaments called loudly for some simplification. The same substance should not be put on the market under different proprietary names. There should also be some limit to the putting up of known substances under a proprietary name and so overloading the pharmacy shelves. The public was protected against poisoning by the Pharmacy and Poisons Act, which confined the sale of poisons to duly qualified pharmacists. There was a strong case for much wider control. It would be in the interest of the community that the dispensing and distribution of all medicaments should be similarly confined to pharmacists. Though they might know little or nothing about pathology and should not presume to diagnose or prescribe, they knew enough to be able to warn a purchaser that the article he wanted was contraindicated.

Red Cross Relief Fund

The British Red Cross Society has issued an appeal for funds, stating that in this war it is certain there will be vast suffering and distress and that the relief of the sick and wounded of the fighting forces and of the civilian population will call for much voluntary effort and financial support. Considerable voluntary help has already been secured, but it remains to find the money necessary to pursue the work. In the great war and indeed at all times appeals made by the British Red Cross Society have obtained a good response. Though the fund was opened only a few days ago, \$375,000 has already been subscribed. Individual donations are as high as \$5,000.

Royal College of Surgeons Takes Precautions Against Air Raids

The more valuable contents of London's museums, libraries and art galleries which would be irreplaceable if destroyed by air raids have been removed to places of safety in basements or to the country. The world-famous Hunterian collection of surgical specimens at the Royal College of Surgeons has been removed to a bomb-proof vault in the college basement. All the more important manuscripts, books and pictures in the college library have been sent to the country.

BERLIN

(From Our Regular Correspondent)

Aug. 24, 1939.

Meeting of Neurologists and Psychiatrists

The Society of German Neurologists and Psychiatrists met this year in Wiesbaden. The president, Professor Rüdin, Munich, pointed out that psychiatry in its efforts for improving racial hygiene performed a timely and progressive service. He credited psychiatry with having been the first division of medicine to point out to the state and the national socialist party the dangers latent in psychopathic persons and to give impetus to the well known legal measures taken. It is fallacious to assume, he said, that psychiatry would become increasingly superfluous, because psychopaths according to the laws governing racial hygiene would soon die out. This assumption involves the danger of deterioration for the psychiatric profession, whereas psychiatry requires the most competent physicians, because it deals with many dangerously ill with hereditary psychoses. "The individual therapist may bungle and mar

one or two human lives, but a poor psychiatrist, whole generations." Rüdín warned against undermining the reputation of psychiatrists.

Scientific attention was given, especially, to the psychic disorders attending advancing years. Max Bürger, the Leipzig clinician, treated the subject from the pathophysiologic point of view. He pointed out, as the basis of his own investigations, that processes characteristic of old age begin in youth and represent a basic phenomenon of life. Ferdinand Kehrer, psychiatrist in Münster, treated the subject from the clinical point of view and presented a systematic account of mental diseases in later life. A. von Braunmühl, Eglfing, Bavaria, showed how precipitations and swellings, modifications in the dispersion rate of the colloidal brain substance and other changes of a colloid chemical nature manifest themselves. G. Gischof-Kutzenberg spoke on the hereditary relations of the psychoses of advancing years. A special position must be accorded to involuntal depressions. Our knowledge, he said, of climacteric and pre-senile psychoses is still fragmentary. Besides, it appears that manic-depressive psychoses that make their first appearance in advancing years require special classifications and do not fit in the frame of hereditary manic-depressive insanity.

Seventieth Birthday of Prof. F. K. Kleine

One of the most deserving of German tropical scientists and for many years collaborator of Robert Koch, Prof. Friedrich Karl Kleine, has celebrated his seventieth birthday, far from his native land, in San Carlos on Fernando Poo (Spanish West Africa), where he is engaged in research work. When an officer in the public health service he was ordered in 1900 to report to the Robert Koch Institute in Berlin, where he soon became a co-worker of Robert Koch in his investigations of the significance of tuberculosis of cattle for human beings. In 1903-1904 he accompanied Koch to Rhodesia and Egypt on the expedition to study coastal fever in cattle and in 1906-1907 to East Africa to study trypanosomiasis. In 1908-1913 Kleine was in charge of the German campaign in East Africa for combating trypanosomiasis and was extraordinarily successful in his scientific activity. The best known result of this activity was the discovery that the agent must pass in the tsetse fly through an evolution similar to that of the malarial parasite in the anopheles mosquito. During the World War Kleine was ranking physician of the German forces in Cameroon. After the war he became divisional director and subsequently president of the Robert Koch Institute for Infectious Diseases in Berlin until his retirement from public service in 1934 on reaching the retirement age. Kleine enjoys an international reputation.

Small Families of Physicians

According to a report that appeared in *Volk und Rasse*, families of physicians are among the smallest of the German population. In 1938 about 21 per cent of the 27,800 physicians of Germany, exclusive of Austria and the Sudetenland, had no children. Fifty per cent had only one or two children; only 23 per cent had three or four children. Large families of five or six children were found in only 4.5 per cent. Conditions in Berlin, Munich and Leipzig were especially bad. Berlin with 32.2 per cent and Munich with 32 per cent showed the largest percentages in marriages without children.

Diabetic Retinitis

Dr. Reinhold Braun has treated diabetic retinitis in a critical examination of the 770 diabetic patients in Professor Umber's ward in the Hospital Westend in Berlin. One hundred and fifteen of these patients had modifications of the retina. Insulin produced no change. Older patients and those with serious diabetes were more frequently affected than younger ones. Of the factors contributing to metabolic disturbances in diabetes, acidosis and the secretion of ketone bodies seem to be most

causative of diabetic retinitis. Perhaps changes in the vascular system of the retina play a part; hypertonia is not involved. Moreover, a certain effect on the evolution of diabetic retinitis seems also to be attributable to the excretory functioning of the kidneys and to disturbances in the sympathetic nervous system and in the balance between the hormones of Langerhans' islands and the chromaffin system. Treatment of diabetic retinitis is almost completely unavailing; however, insulin is in no wise injurious to the retina.

Tuberculosis Among Sailors

The fight against tuberculosis occupies a prominent position in the hygienic welfare work connected with social insurance. The sailors' vocation is not favorable to tuberculous men, but quite the contrary, because of the strenuous work and the constant exposure to cold. Recognizing this the sailors' union about a year ago undertook to examine crews in active service for tuberculosis. About 18,000 examinations have been completed. Hereafter sailors will no longer be employed on German ships without certificates of examination. No charges are made to sailors for these tests.

Professor Riecke's Seventieth Birthday

Prof. Erhard Riecke, dermatologist, completed his seventieth year May 11. He had been full professor since 1920 in the department of dermatology and venerology in Göttingen and recently retired on reaching the retiring age. Riecke made a reputation by the publication of a textbook on cutaneous and venereal diseases, a book that enjoyed numerous editions and is the most widely used German textbook in this field.

Social Service in New Zealand

The social security scheme in New Zealand this year will cost £12,000,000, distributed over a population of only one million people. Payments include £6,910,000 in old age benefits, £1,050,000 for invalids, £1,010,000 for widows, £508,000 for sickness benefits, £306,000 for maternity benefits, £738,000 for hospitals, £100,000 for medical expenses and £459,000 for administrative expenses. Of the total cost £5,550,000 will be obtained from wages, £3,050,000 from other income and £2,000,000 from the consolidated fund. The budget has been received with hostility by the business sections of the community. The decision to increase the tax on gasoline by fourpence per gallon and that on beer by sixpence per gallon is particularly unpopular. Prof. A. H. Locker, leading economist, has stated that the budget appears to be mainly a stop gap and that the government is merely deferring the evil day when it will have to face its difficulties.

MATERNITY SERVICES CONTRACTS

After much dissension, the medical profession has now approved by ballot the acceptance of contracts for maternity services, under the social security scheme, and the government has been asked by the profession to legislate to make contracts binding on all practitioners who normally undertake maternity work. The effect will be that all mothers who desire state assistance will have this right, although any who do not wish to take the benefit may make independent arrangements. This decision, however, does not dispose of the larger question, which is still at issue between the British Medical Association and the government over the inauguration of the universal practitioner service. A powerful coercion on the profession may, however, come from the public. Several letters appearing in the press have pointed out that the community is now paying the social security tax but still has to pay for the services of a doctor. The writers suggest that instead of paying for medical

services twice over, as at present, doctors' bills should be ignored in future. If this idea "catches on," the British Medical Association will be forced irrevocably to obey the voice of the people as expressed in a democratic election.

Plumbism and Chronic Nephritis

As long ago as 1892, attention was drawn to the prevalence of lead poisoning among children in Brisbane. It was not until 1929, however, that serious attention was paid to the possible association of plumbism and chronic nephritis. Now the commonwealth department of health has issued a brochure on the subject consisting of a report by Dr. R. Elliott Murray including details of a method for the estimation of lead in biologic materials. At the present time about ninety persons below the age of 30 years and approximately the same number between the ages of 30 and 50 die annually from nephritis in Queensland, in excess of the number that would succumb to the disease were the death rate the same as that of Great Britain. The death rate below the age of 30 years is about the same as it was from 1917 to 1926, but above that age it has been steadily tending to increase. During the same period the annual total death rate from chronic nephritis at all ages has increased from an average of 403.5 to 558 per million of population. Murray has shown beyond doubt that plumbism does occur in children in Queensland. Investigating paint as a source of lead, he found that paint which retained its glossy hard surface would not yield any appreciable amount of lead on being rubbed with saliva moistened fingers. On the other hand, when the paint became weathered the danger rapidly became serious. He makes the observation that a weathered paint containing a low percentage of lead may yield more lead on being rubbed than a paint containing a higher proportion of lead but remaining in a better condition and suggests that the 5 per cent limit to the lead content of paint for veranda railings, gates and fences as enacted in 1923 may still allow dangerous amounts of the material to become available to children after weathering has occurred.

Considering the question whether plumbism is a factor in the causation of chronic nephritis in Queensland, Murray concludes that from a consideration of the past history of cases of nephritis and the later progress of cases of plumbism, together with the results of biochemical examination of nephritis cases, lead poisoning in childhood is a major factor in the causation of the abnormal Queensland incidence of chronic nephritis. Although it would appear possible that it is the sole factor responsible, it cannot be stated dogmatically that such is the case. It would appear probable that any other factor which can cause renal damage could act in conjunction with lead to aggravate the condition. The role of climate with its possible effects on acid-base and mineral metabolism cannot be accurately assessed, but while it may act as an adjuvant to other sources of renal damage there is sufficient evidence to allot to it a major role.

A National Memorial to Sir Truby King

The Royal New Zealand Society for the Health of Women and Children, more commonly known as the Plunket Society, has launched an appeal for a national memorial to its founder, the late Sir Truby King. Such an appeal has the whole-hearted support of the medical profession in New Zealand. It has been decided that £2,000 of the sum obtained shall be set aside to assist in the upkeep and maintenance of the home of Sir Truby King in Wellington, which he bequeathed to the society. A further £2,500 will be invested for the purpose of providing a postgraduate course for nurses trained in the Plunket system of child welfare, while smaller sums will be expended on a monument and a portrait of the founder of the Plunket Society.

It is too soon after the death of Sir Truby King to assess finally and with any accuracy his contribution to medical science. We can, however, pay homage to his personal attri-

butes. His untiring energy and selfless devotion to an ideal were known all over the world. He possessed a genius for organization of a high order, and to a remarkable degree he wielded the power of infusing others with his own enthusiasm. He was held in great honor by members of his profession, and their response to the appeal made by the council of the Plunket Society no doubt will be spontaneous.

Medical School for Queensland

The official opening of the new medical school of the University of Queensland on August 11 marks the final achievement in the campaign for the provision of facilities for medical education in this state. When in October 1936 the Faculty of Medicine was inaugurated, that function marked the successful issue of representations which had their commencement as early as the foundation of the university itself. The first actual proposals in 1913 were interrupted by the outbreak of the great war and shortly after its conclusion in 1922 arrangements were made for anatomic demonstrations to be given to certain of the dental students at the university. By slow degrees from this small beginning grew the skeleton structure of a medical course. In 1936 it was suggested that the inauguration of the faculty was of such importance that even makeshift provision, so far as buildings were concerned, would be better than delay, but the government after due consideration decided to provide buildings worthy of the new venture, and the recently completed medical school is a magnificent tribute to their recognition of its scope and importance. The building is a dignified example of Renaissance architecture and has been designed to incorporate all modern improvements in laboratory and lecture room design.

The Hospital Habit

A generation or two ago it was the rule rather than the exception for residents of Copenhagen to be sick at home. Now most of them, when seriously ill, prefer hospital to home treatment. Support of these remarks is to be found in a study Dr. Povl Heiberg has undertaken with the object of showing how the hospital habits of his fellow countrymen have changed. He has studied his material in five year instead of one year periods to avoid the pitfalls inherent in small figures. In the five year period 1881-1885 only 29 per cent of all the deaths in Copenhagen occurred in hospitals, whereas the corresponding figure for the five year period 1931-1935 was 67 per cent. At the end of the last century only one in every three of the population of Copenhagen died in a hospital, whereas now two in every three do so.

This remarkable change has not been effected in an equal degree by the various diseases responsible for the deaths on record. Hospital treatment for such a disease as croupous pneumonia, for example, is not so much more common now than it was in the five year period 1886-1890, when 26 per cent of all the cases were admitted to a hospital. The corresponding figure for the five year period 1931-1935 was 37 per cent. On the other hand, only 28 per cent of all the deaths from pulmonary tuberculosis between 1896 and 1900 occurred in hospitals, whereas between 1931 and 1935 as great a proportion as 75 per cent did so. Indeed, in the case of syphilis and gonorrhea the tendency seems to be away from inpatient hospital treatment in favor of outpatient hospital treatment. Formerly, every fifth case of scabies was treated in hospitals, whereas now, thanks in large part to the quick efficiency of modern treatment, it is found necessary to provide hospital treatment for only some 3 per cent of these cases. This is just as well, for there are still some 5,000 to 6,000 cases of scabies notified in Copenhagen every year in spite of the compulsory treatment provided for this disease.

Denmark's Dietetic Habits

Dr. Johanne Christiansen, who seems to have become the uneasy dietetic conscience of her country, continues to wage war on her fellow countrymen's sins of omission and commission over the dinner table. Her special aversion is Dr. Hindhede, who did so much a generation ago to promote vegetarianism in Denmark. The duel between these two protagonists has been carried on outside as well as inside Denmark, and in 1934 Dr. Christiansen issued in a German medical journal a pug-nacious article with the ominous heading *Mein Kampf gegen Hindhede*. This autumn she has issued in Danish a fairly comprehensive summary of the faith which is in her. The Danes, she says, are laboring under the most embarrassing handicap of utterly misguided doctrines concerning the very elements of nutrition. They are fed on margarine, bacon, refined sugar and sophisticated flour, whereas what they need in the place of these mischief-making foods are milk, eggs, cheese, meat, fish, fruit, vegetables and wholemeal bread. The Danes in the Middle Ages lacked vitamin C and, before the introduction of potatoes, were subject to scurvy. The Danes of today suffer from a host of ills because natural and protective foods have largely been replaced by artificial foods from factories. As a race, Danes are far too plump, and it is no mere chance that in some Danish hospitals about 10 per cent of all the diagnoses on admission are obesity. It is temptingly easy for the medical profession to cope with this situation by prescribing various vitamin preparations with a view to repairing the mistakes of the menu, but how much more rational it would be to revise the menu and thus to make proprietary vitamin preparations superfluous! When a Dane falls ill, it has heretofore been the practice in hospital dietaries to reduce rather than increase his supply of vitamins, and he has been fed on pappy foods instead of on plenty of milk and on meat soups, which are an excellent vehicle for vegetables. Dr. Christiansen would also like to see her countrymen producing home-brewed beer containing plenty of vitamins B and C. The old Danish custom of mixing home-brewed beer with milk might well, she says, be revived.

Vitamin K Deficiency in Infancy

A good example of effective team work in Copenhagen is to be found in the hospital for children's diseases under Professor Bloch, the University Biochemical Institute under Professor Ege, and the obstetric departments A and B of the Rigshospital under Professor Hauch and Professor Rydberg respectively. The coordinators of this work are Drs. Dam, Tage-Hausen and Plum. Employing the technic elaborated by Dam and Glavind for the quantitative demonstration of prothrombin in the blood, they have succeeded in linking up in a clinical triad the following conditions heretofore regarded as independent of one another: icterus gravis neonatorum, anaemia neonatorum and hydrops congenitus. The connecting link, demonstrable in each case, is a well defined hypoprothrombinemia. Administration of vitamin K to the patients suffering from these conditions was so effective in rapidly raising the quantity of prothrombin in the blood that it seemed likely that these patients must have been suffering from vitamin K deficiency.

Last April a 26 day old boy was admitted to Professor Bloch's hospital suffering from jaundice, anemia and hemorrhages. Vitamin K deficiency being suspected, the rate of coagulation of the blood was investigated, the content of prothrombin in the blood being measured. It proved to be much reduced, and the child was therefore treated with vitamin K. Within a day of this treatment the hemorrhages ceased. This striking observation led to quantitative analyses of prothrombin in the blood of healthy children and others suffering from such conditions as icterus gravis neonatorum, anaemia neonatorum and congenital hydrops. The conclusion drawn from these studies is that under normal conditions there is a shortage of vitamin K

during the first few days after birth. No depot of vitamin K existing in the baby's body at birth, and the supply of this vitamin depending on the mother's milk and bacterial activity in the intestine, this temporary shortage of vitamin K is inevitable and is repaired only after the baby has begun to feed and the normal bacterial activities of the contents of the intestines have set in.

BUCHAREST

More Than a Thousand Centenarians in Rumania

The Central Statistical Institute, led by Prof. D. Sabin Manuila, has published a bulky volume with the title "Breviarul Statistic al Romanici." According to this book the number of persons in the kingdom reached in this year the figure of 19,535,398. Of these about 80 per cent, that is 15,926,178, live in villages and the number of the urban population is only 3,609,220. The number of children under 9 years of age is 4,822,698 and of persons from 70 to 80 is 323,355, from 80 to 90 is 61,212 and from 90 to 100 is 8,030. The number of persons over 100 years of age is 1,074. Since the last census in 1930 the birth rate has fallen from 35.2 per thousand to 31.5 per thousand. The death rate, however, did not follow the rate of decrease of the birth rate, decreasing only from 21.2 to 19.8.

Marriages

HENRY FRANZ ALBRECHT JR., Troy, N. Y., to Miss Catherine Elizabeth McArdle of Lawrence, Mass., recently.

JAMES D. SORRY, Madisonville, Ky., to Mrs. Margaret Johnson of Boston at Lexington, Ky., September 16.

WATSON WHARTON, Smithfield, N. C., to Miss Eddythe Hawkins of Johnson City, Tenn., August 17.

CHARLES McCRAW WOOD to Miss Florence Swan, both of Maroa, Ill., at Rochester, Minn., August 15.

SAMUEL A. ALESSANDRA, Dallas, Texas, to Miss Ethel Evelyn Prince of Timpson, September 1.

IVAN VINCENT BAMBERGER, York Haven, Pa., to Miss Myre E. Painter of York, September 20.

EDWARD KIRBY LAWSON, Penbrook, Pa., to Miss Bessie B. Stoner of Philadelphia, August 4.

ERNEST E. WIESNER, Brockton, Mass., to Miss Doris Billings of Lynn, September 8.

ALBAN PAPINEAU, Plymouth, N. C., to Miss Jeannette Edwards of Ayden, August 30.

EDWIN E. MCNIEL to Miss Marjorie Robertson, both of Honolulu, Hawaii, July 16.

ELLWOOD W. GODFREY, Ambler, Pa., to Miss Sophia Moore of Wynnewood, August 28.

WILLIAM N. GILMAN, Wenona, Ill., to Miss Dorris Louise Lec of Normal in August.

GRANT SANGER to Miss Margery Edwina Campbell, both of New York, September 30.

ALFRED A. GELLHORN, St. Louis, to Miss Olga Frederick of Nokomis, Ill., August 4.

JOSEPH MARCOVITCH, Dwight, Ill., to Miss Lillian Ganzer at Brooklyn, September 6.

WALTER J. PHILLIPS, Chicago, to Miss Helen Petkus of Cicero, Ill., August 20.

JOSEPH N. ROSE, Evarts, Ky., to Miss Myrtle A. Kennedy of Harlan, recently.

NATHAN R. ABRAMS to Miss Edna Silverstein, both of Cincinnati, August 20.

HANS SYZ to Miss Emily Sherwood Burrow, both of New York, August 12.

JOEL WRIGHT to Miss Onie May, both of Alpine, Texas, August 6.

Deaths

Harvey Cushing, one of the most distinguished of all surgeons in operative procedures on the brain, recognized as an accomplished author, educator, philosopher and leader, died in New Haven, Conn., Saturday, October 7, of coronary thrombosis. He was the fourth Cushing in a direct line to win distinction in a medical career.

Dr. Harvey Cushing was born in Cleveland, April 8, 1869, the ninth child in his family. His well known brother, Edward F. Cushing, M.D., a pediatrician, died in 1911; his father, Henry K. Cushing, formerly professor of obstetrics and gynecology in Western Reserve University School of Medicine, died in 1910; his grandfather Erastus Cushing died in 1893, and his great grandfather David Cushing Jr., of Massachusetts, died in 1840.

After receiving the bachelor of arts degree at Yale in 1891, where incidentally he also played baseball, Dr. Harvey Cushing

graduated from Harvard Medical School in 1895, receiving the degrees of master of arts and doctor of medicine. He entered the Massachusetts General Hospital as surgical intern, working with Dr. J. C. Warren. In 1896 he went to Baltimore as junior assistant in the surgical service of Halsted, becoming resident surgeon in 1897 and developing as instructor in surgery, assistant in surgery and associate in surgery. He made the first roentgenograms that were made at Johns Hopkins Hospital and did experimental studies on gallstones, the bacteriology of the alimentary canal, and cocaine anesthesia. In 1900 he studied abroad, traveling with Drs. William Osler and Thomas McCrae. On this trip Dr. Cushing studied in England, France and for a year in Kronecker's laboratory in Berne. Here he carried out some investigations suggested by Kocher on the physiologic relationships of intracranial tension. This work he continued in the laboratory of Mosso in Turin, Italy, and then for four months he worked with Sherrington in Liverpool studying the motor cortex in anthropoids. Late in 1901 he returned to Baltimore and asked for the post of neurosurgeon in the clinic. Here he remained until 1912,

during which time he became associate professor of surgery. He gave the Mutter lecture in Philadelphia in 1901. He became a member of the American Neurological Association in 1903 and president in 1923, a charter member of the American Society of Clinical Surgery in 1903 and president in 1921, a member of the American Physiological Society in 1905, a fellow of the American Surgical Association in 1906 and president in 1927. Dr. Cushing was secretary of the Section on Surgery and Anatomy of the American Medical Association in 1906-1907. He gave the Carpenter lecture in New York in 1906 and the W. M. Banks Memorial lecture in Liverpool in 1909 and the Harvey lecture in New York in 1910. During this period he developed his marvelous technic in neurosurgery. The earlier operations were failures, but Dr. Cushing's courage, precise technic and remarkable spirit began to yield success and his fame spread widely. During this period he developed and described the subtemporal decompressive operation and perfected hemostasis in operations on the brain and new technics for suture. His contributions to the physiology of the brain, the spinal fluid and the pituitary body were fundamental.

In 1912 Dr. Cushing became Moseley Professor of Surgery at Harvard and Surgeon-in-Chief to the Peter Bent Brigham Hospital. He received the master of arts from Yale in 1913, gave the oration of surgery at the International Congress of

Medicine in London in 1913 and was made a fellow of the Royal College of Surgeons, of the American College of Surgeons of which he became president in 1922 and of the Institute of Hygiene in London. He gave the Weir Mitchell lecture in Philadelphia in 1914 and was elected at that time a foreign member of the Société de neurologie in Paris, of the American Academy of Arts and Sciences and of the Washington Society of Arts and Sciences.

In 1914 came the great war, during which the remarkable service rendered by Harvey Cushing was universally recognized. He served with distinction in the British Expeditionary Force; he became surgical director of the United States Base Hospital No. 5 and was appointed senior consultant of neurologic surgery with the American Expeditionary Forces with the rank of colonel. For these services he received the Distinguished Service Medal of the United States, the Companion of the Bath of England, and Officer of the Legion of Honor of France. His war service is reflected in his recently published "Diary of a War Surgeon." Evidently this service in the war was a terrific

physical stress, for Dr. Cushing returned to Boston in 1919 suffering from peripheral neuritis, which was to handicap him during the remainder of his career. Nevertheless in the years from 1919 on he worked indefatigably. He turned to an interest in the history of medicine and made a complete collection of the writings of Vesalius. At the same time he developed a surgical team for neurologic surgery and himself studied intimately the microscopic anatomy, gross anatomy, pathology and physiology of conditions within the brain. Young surgeons flocked to him from all over the world. Today his pupils have won distinction as neurosurgeons. In 1918 he became fellow of the Royal College of Surgeons of Ireland. He received the degree of doctor of science from Washington University in 1919 and in the same year the honorary doctor of laws from Western Reserve University, doctor of science from Yale and Doctor of Science of Queen's University, Belfast. In 1920 he received the degree of honorary doctor of laws from Cambridge and in 1921 was made honorary fellow of the Medical Society of London, giving the chief oration in 1927. In 1921 he became a corresponding member of the Medical Society of Vienna and

in 1922 a Charles Mickle Fellow of the University of Toronto, also the Cavendish Lecturer (London) and was awarded the title of Honorary Perpetual Student of St. Bartholomew's Hospital, London. He also became a corresponding member of the Medico-Chirurgical Society of Edinburgh.

After the death of Sir William Osler, Lady Osler turned over all her data relative to her distinguished husband to Harvey Cushing and he took up the task of preparing the famous biography. This book appeared in 1925 in two large volumes and was awarded the Pulitzer Prize as the best biographic writing of the year.

In the meantime he continued his surgical operations and received additional honors. In 1923 he became a foreign member of the Académie de médecine of Paris and a fellow of the Association of Surgeons of Great Britain and Ireland. In 1924 he gave the Cameron Prize Lecture at Edinburgh and was elected a corresponding member of the Società medico-chirurgica di Bologna. In 1926 he received the honorary doctor of laws from the University of Glasgow, in 1928 the doctor of laws from Jefferson Medical College and the Doctor of Medicine from John Casimir University of Lwow, Poland. In the following year he was made honorary fellow of the Royal Society of Medicine of England, of the Royal Academy of Medicine of Ireland, master of surgery of Trinity College, London, doctor of laws

HARVEY CUSHING, M.D., 1869-1939

of the University of Edinburgh and a fellow of the Royal College of Surgeons of Edinburgh. In 1929 there was published in his honor a special number of the *Archives of Surgery*, dedicated to his sixtieth birthday. A similar festschrift was later published by *Acta medica Scandinavica*. In 1932 Dr. Cushing retired from his posts in Boston and became Sterling professor in the School of Medicine of Yale University, teaching neurology and the history of medicine and holding this position until 1937, when he became emeritus professor.

In addition to the famous "Life of Sir William Osler," Dr. Cushing published "The Pituitary Body and Its Disorders" in 1912, "Tumors of the Nervous Acusticus" in 1917, with Dr. Percival Bailey "A Classification of the Gliomata" in 1925, collected essays under the title "Consecratio Medici" in 1928, "Intracranial Tumors" in 1932, and in the same year a book on "The Pituitary Body and the Hypothalamus."

In July 1938 Oxford University conferred on him the honorary degree of doctor of science, on which occasion great physicians and surgeons from all over the world assembled to honor him. It was pointed out that his former pupils hold positions in Brussels, Louvain, Amsterdam, Manchester, Edinburgh, Leeds, London, Oxford and Newcastle-on-Tyne as well as in most of the leading clinics in the United States. There are honorary Cushing clubs in many medical schools dedicated to his work and his memory.

Since 1931 great universities have continued to honor him. He gave other lectures, such as the Donald Balfour Lecture of the University of Toronto. In 1933 he was honored in Paris, at which time he was presented with the original copy of Clemenceau's thesis for the doctorate in medicine, written in 1865. He received also the honorary degree of doctor of laws from Northwestern University and the honorary degree of doctor of medicine from Budapest.

Of recent years Dr. Cushing had shown special interest in maintaining the traditional professional status of the physician and surgeon and he had given freely of his time and of his efforts in this endeavor. An essay called "Medicine at the Crossroads," published in *THE JOURNAL*, May 20, 1933, page 1567, defined his point of view. In this essay he wrote: "Those who deal with the science of society deal with something that actually does pulsate with so short a time cycle that conditions almost from year to year are never quite the same, so that our theories of today are likely to need modifying tomorrow. What this puzzled world needs perhaps is more study of the past, fewer commissions and surveys of the present, and a greater number of philosophically minded, self-supporting and law-abiding persons who can see all round their particular problem and independently devote themselves to it as do most doctors."

In the presence of such a record and such a career, in the light of such a character and such a man, superlatives fail. Great epochs in medicine are marked by the names of physicians whose careers have made these epochs. With Dr. Harvey Cushing, surgery of the brain became for the first time scientifically established. Of him it may be truly said that he was in all that he attempted greatest of the great.

Andrew Stewart Lobingier, Los Angeles; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889; member and past president of the Pacific Coast Surgical Association; fellow of the American College of Surgeons; formerly on the staffs of the Hospital of the Good Samaritan and the Hollywood Clara Barton Memorial Hospital; at one time lecturer in surgery at the University of Southern California School of Medicine; professor of bacteriology and pathology, Gross Medical College, Denver, 1889-1892; professor of pathology, University of Colorado School of Medicine, Denver, 1892-1894, and professor of surgery, 1894-1902; formerly secretary of the Colorado State Medical Society; aged 76; died, July 31, of arteriosclerosis.

Herbert Peter Howell Galloway, Winnipeg, Man., Canada; Victoria University Medical Department, Coburg, Ont., Canada, 1887; formerly associate professor of clinical surgery (orthopedic), University of Manitoba Faculty of Medicine; served during the World War; served as president of the Manitoba Medical Association and the Winnipeg Medical Society; member of the Clinical Orthopedic Society and the American Academy of Orthopedic Surgery; past president and vice president of the American Orthopedic Association; fellow of the American College of Surgeons; aged 73; was the original orthopedic surgeon at the Children's Hospital; on the staff of the Winnipeg General Hospital, where he died, July 13, of cerebral hemorrhage.

George Samuel Bel • New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1893; professor of medicine at the Louisiana State University Medical

Center; assistant in medicine, 1894-1900, instructor in medicine, 1900-1904, assistant professor of medicine, 1904-1910, professor of clinical medicine, 1910-1918, professor and head of the department of medicine, 1918-1924, and emeritus professor of medicine at his alma mater; president of the Louisiana State Board of Medical Examiners; past president of the Louisiana State Medical Society; director of the Charity Hospital; aged 67; died, August 10, of coronary thrombosis.

Lena Kellogg Sadler • Chicago; American Medical Missionary College, Chicago, 1906; fellow of the American College of Surgeons; past president of the Medical Women's National Association and the Chicago Council of Medical Women; attending gynecologist to the Columbus Hospital; attending surgeon to the Women and Children's Hospital; author of "How to Feed the Baby" published in 1925, author with Dr. W. S. Sadler "The Mother and Her Child" published in 1916 and "Psychiatric Nursing" published in 1937, and other books; aged 64; died, August 8, of carcinoma of the breast.

Milton Arlenden Bridges • New York; Columbia University College of Physicians and Surgeons, New York, 1919; assistant professor of clinical medicine at the New York Post-Graduate Medical School, Columbia University; fellow of the American College of Physicians; served in various capacities on the staff of the Riker's Island Hospital of the Department of Correction; consulting physician to the Sea View Hospital, Staten Island; author of "Dietetics for the Clinician" and "Food and Beverage Analyses"; aged 45; died, August 19, of chorio-epithelioma.

George Hudson McLellan • Lieutenant Colonel, U. S. Army, retired, San Diego, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1907; was commissioned in the medical corps of the U. S. Army as a first lieutenant in 1909 and retired as a major in 1922 for disability in line of duty; served during the World War; was appointed lieutenant colonel under the special act of June 21, 1930; aged 55; died, July 14, of coronary occlusion and cerebral hemorrhage.

William Louis Clapper, St. Louis; Washington University School of Medicine, St. Louis, 1904; formerly senior instructor in obstetrics, gynecology and abdominal surgery, St. Louis University School of Medicine; on the staff of St. Luke's Hospital; assistant gynecologist and obstetrician to St. Mary's Group of Hospitals; member of the Missouri State Medical Association; fellow of the American College of Surgeons; aged 61; died, August 4, of Parkinson's disease.

Leo Thomas Perrault, New York; Jefferson Medical College of Philadelphia, 1908; associate professor of clinical otolaryngology at the New York Post-Graduate Medical School, Columbia University; member of the Medical Society of the State of New York; on the staffs of St. Luke's Hospital, St. Francis Hospital, Post-Graduate Hospital and Metropolitan Hospital; aged 55; died, August 25, in Mantoloking, N. J., of coronary thrombosis.

Bernhard Friedlaender • Detroit; Baltimore Medical College, 1898; member of the Radiological Society of North America; formerly attending obstetrician and gynecologist at the Women's Hospital, and senior surgeon at the Highland Park (Mich.) Hospital; aged 68; died, August 14, in Rochester, Minn., of thrombosis of the mesenteric vein, gangrene of the intestine and peritonitis.

Clyde I. Allen • Detroit; Johns Hopkins University School of Medicine, Baltimore, 1921; fellow of the American College of Surgeons; member of the American Association for Thoracic Surgery; for many years on the staff of the Henry Ford Hospital; aged 45; died, August 2, of cerebral hemorrhage, arteriosclerosis and hypertension.

Joseph Dixon Purvis • Butler, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; past president of the Butler County Medical Society; on the staff of the Butler County Memorial Hospital; aged 56; died, August 3, in St. Mary's Hospital, Rochester, Minn., of subarachnoid hemorrhage.

Judson Albert Palmer, Arcadia, Wis.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890; member of the State Medical Society of Wisconsin; served during the World War; formerly mayor, bank president and health officer; aged 70; died, July 7, of heart disease.

Carl O. Hertzman, Ashland, Wis.; College of Physicians and Surgeons, Baltimore, 1900; member of the State Medical Society of Wisconsin; city health officer; aged 72; on the staffs of St. Joseph's Hospital and the Ashland General Hospital, where he died, July 25, of chronic nephritis and uremia.

Carroll J. Tucker, San Diego, Calif.; Indiana University School of Medicine, Indianapolis, 1914; served during the World War; aged 52; died, July 18, in the Veterans Administration Facility, West Los Angeles, of carcinoma of the prostate with multiple metastases.

Edwin Jason Brewer, Shabbona, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; member of the Illinois State Medical Society; for many years mayor; aged 64; died, August 6.

Ira Ayer, San Diego, Calif.; Long Island College Hospital, Brooklyn, 1892; veteran of the Spanish-American War; at one time personal physician to the King of Siam; aged 70; died, July 9, in the United States Naval Hospital, of myocarditis.

Truman Osborne Boyd Ⓢ Long Beach, Calif.; University of Louisville (Ky.) Medical Department, 1902; past president of the Idaho State Medical Association; aged 69; on the staff of St. Mary's Hospital, where he died, July 8, of lymphosarcoma.

Edmund Francis Fusco Ⓢ Elizabeth, N. J.; Columbia University College of Physicians and Surgeons, New York, 1934; member of the Medical Society of the State of New York; aged 29; died, July 23, at St. Elizabeth Hospital.

Thomas Francis Gartland Ⓢ White River Junction, Vt.; University of Vermont College of Medicine, Burlington, 1893; aged 70; died, July 7, at the Mary Hitchcock Memorial Hospital, Hanover, N. H., of coronary occlusion.

Philips Josiah Edson Ⓢ Pasadena, Calif.; University of California Medical School, San Francisco, 1924; on the staffs of St. Luke's Hospital and the Huntington Memorial Hospital; aged 42; died, July 6, in San Marino.

Gustave Adolph Fritz, Baltimore; University of Maryland School of Medicine, Baltimore, 1915; member of the Medical and Chirurgical Faculty of Maryland; formerly coroner; aged 48; died, July 9, of heart disease.

John Walter Fitz-Gerald Ⓢ Buffalo; Trinity Medical College, Toronto, Ont., Canada, 1900; aged 67; died, July 12, at his summer home at Wasaga Beach, Ont., of coronary thrombosis.

Edgar August Degenhardt Ⓢ Chicago; Chicago Medical School, 1921; served during the World War; aged 43; died, August 14, at his home in Oak Park, Ill., of coronary thrombosis.

Oliver H. Thompson, Marion, La.; University of Nashville (Tenn.) Medical Department, 1884; formerly bank president and member of the school board; aged 82; died, July 28.

Charles W. Montgomery, Washington, D. C.; National Homeopathic Medical College, Washington, D. C., 1894; aged 71; died, July 11, of cerebral hemorrhage and arteriosclerosis.

Ephraim Gardner Kimball, Washington, D. C.; Columbian University Medical Department, Washington, D. C., 1888; aged 81; died, July 17, of chronic nephritis and pyelitis.

Ira De La Matter, Long Branch, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1911; aged 56; died, August 3, in the Toronto Western Hospital.

Laurence A. Saunders, Los Angeles; Louisville (Ky.) Medical College, 1876; aged 85; died, July 24, of pulmonary tuberculosis.

Colston L. Dine, Minster, Ohio; Medical College of Ohio, Cincinnati, 1886; aged 81; died, August 1, of cerebral arteriosclerosis.

William John Hunter Emery, Porterville, Calif.; Cleveland University of Medicine and Surgery, 1882; aged 78; died, July 31.

Henry Applegate Lacy Ⓢ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1891; aged 75; died, July 30.

Loyal Low Likien, Smithmill, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1901; aged 69; died, July 2.

Robert H. McLean, Lillington, N. C. (licensed in North Carolina in 1882); aged 86; died, July 14, of myocarditis.

Walter J. Proper, Pleasantville, Pa.; Starling Medical College, Columbus, Ohio, 1883; aged 79; died, July 20.

Robert Herman Dengler, Philadelphia; Jefferson Medical College of Philadelphia, 1887; aged 79; died, July 19.

CORRECTION

Dr. Fisher Not Dead.—Dr. James Coleman Fisher of Jefferson, Ohio, whose death was reported in *THE JOURNAL* September 30, page 1346, is not dead. His death was erroneously reported by the Decatur (Ill.) *Herald-Review*, August 6.

Correspondence

POTASSIUM CHLORIDE IN ALLERGY

To the Editor:—In *THE JOURNAL*, September 2, appeared a communication by Dr. David Louis Engelsher in criticism of my report on potassium chloride in allergy. Since this might give an erroneous impression, both of the toxicity and of the efficacy of potassium chloride, I feel that some clarification is needed.

Dr. Engelsher has made the simple mistake, against which I warned in my article, of administering potassium chloride in the dry form. He says "The patients were given ten 5 grain (0.3 Gm.) tablets of potassium chloride to be taken, when necessary, three times a day after meals with at least one glassful of water." (By this he probably means 5 grains to a dose rather than 50.) In my article I stressed the necessity for administering it in dilute form, e. g., 5 grains dissolved in a glass of water. This does not mean prescribing a 5 grain tablet to be taken with a glass of water. It is apparent that the severe epigastric pain described by Dr. Engelsher is due, as I have already noted, to his method of administration. Unfortunately, many of the drug houses are now marketing potassium chloride in tablet form without clear instructions that the tablet is to be dissolved before being taken. When properly administered, potassium chloride only rarely produces side effects. The most important of these is the occasional aggravation of asthma, which calls for the immediate cessation of this treatment; other rare effects include diarrhea and urinary urgency. I have not advocated the use of potassium chloride in chronic asthma.

Answers to letters sent to a number of leading physicians in this country indicate a wide divergence of opinion with regard to its efficacy in allergy. Many report gratifying results, particularly in hay fever and allergic rhinitis. On the other hand, many have found it so far completely ineffective. My results continue to be good, although I do have failures. The only published report so far is that of A. F. Abt, who obtained excellent results in twenty cases. I hope that an explanation for this sharp discrepancy of opinion will be forthcoming. Potassium is neither a "cure" nor a "cure-all"; it is apparent, however, from my results as well as from the numerous reports which I have received, that it has given appreciable relief to a large number of allergic patients.

BENSON BLOOM, M.D., Tucson, Ariz.

THE DEGREE OF "DOCTOR" IN DENTISTRY

To the Editor:—The need for safeguarding the title of "doctor" in the interest of public protection and professional dignity was clearly pointed out by Dr. Frederick Juchhoff in his communication "The Degree of Doctor," published in *THE JOURNAL* August 26, page 876. I need add little to support the main thesis. Although I fully approve the spirit of the communication, I wish to recommend a modification of the following statement by the author to give it a sense of greater completeness: "The statutes should prohibit the use of the title doctor in connection with any healing art by one who does not have a regular medical training." By addition of the phrase "and dental training" following "medical training," the dental profession will be given the honor of distinction that American dentistry rightly deserves. As an Associate Fellow, I believe that I express the sentiment of other dental members in the Association.

From observations made in my recent study on dentistry and dental education (*Principles Underlying the Social and Professional Background in the Education of Dentists and Teachers of Dentistry*, thesis, New York University, School

of Education, June 7, 1939) it is noted that in 1940 all dental schools in the United States will require a two year preprofessional course and a four year professional course of training for the practice of dentistry and the degree of Doctor of Dental Surgery (D.D.S. or D.M.D.). The years required for the professional training of the dentist are the same in number as those required of the physician. As indicated by Dr. Fishbein, the medical course in the United States covers four years (Fishbein, Morris: *Do You Want to Become a Doctor?* New York, Frederick A. Stokes Company, 1939, p. 37). The two preclinical years of the four year professional course in dentistry include a considerable portion of subject matter that is identical in content with the first two years of the medical course. In addition to this, almost all dental schools are affiliated with universities. Since the publication of Professor Gies's Carnegie study in 1926 the proprietary dental school of the past has disappeared in the United States.

It is true, as shown in my report, that a large percentage of dentists and dental educators favor maintaining dentistry as an autonomous profession, independent of medical education. It is, however, unanimously conceded that dentistry is a specialty of medicine (not of medical practice) and an acknowledged oral health service. Dentistry has attained a place of scientific recognition to the extent that eleven dentists have considered it worth while to pursue their graduate studies leading to the Ph.D. degree in hygiene, chemistry and surgery. It has been my pleasure to take the Ph.D. degree in education, stressing in the thesis the professional and social significance of dental education.

I suggest that in all considerations of the degree of "doctor," dentistry be given its due recognition and the consideration it deserves. After all is said and done, dentistry is an integral part of the medical profession. It therefore behooves those who write in defense of the title "doctor" not to overlook the honorable degree of doctor in dentistry.

ALFRED J. ASGIS, D.D.S., Ph.D., New York.

VULVOVAGINITIS IN PREGNANCY

To the Editor:—"The Significance of Vulvovaginitis in Pregnancy" by Edward G. Waters and Eakle W. Cartwright (*THE JOURNAL*, July 1, p. 30) does not cover the entire subject; certain points deserve elaboration:

1. Many, if not most, researches of recent date have used Sabouraud's or modified Sabouraud's medium directly for isolation of the yeastlike fungi instead of the method employed by these authors. Their technics might explain this low incidence. Surely those interested in this work would appreciate the authority for the technic advocated in this article. Yeastlike fungi were isolated from 32 per cent of gravid women without vulval symptoms by Plass and his co-workers (*Am. J. Obst. & Gynec.* 21:320 [March] 1931), from 23 per cent of all pregnant women by Weinstein and Wickerham (*Yale J. Biol. & Med.* 10:553 [July] 1938) and from 14 to 41 per cent in different economic and hygienic groups by Woodruff and Hesselstine (*Am. J. Obst. & Gynec.* 36:467 [Sept.] 1938).

2. The relationship of p_n readings to the mycosis is not clear, since these yeastlike organisms will grow in vitro over p_n ranges greater than any reported readings of the vagina (Hesselstine, H. C., and Noonan, W. J.: *J. Lab. & Clin. Med.* 21:281 [Dec.] 1935).

3. The reports of Hesselstine, Borts and Plass (*Am. J. Obst. & Gynec.* 27:112 [Jan.] 1934), Bland, Rakoff and Pincus (*Arch. Dermat. & Syph.* 36:760 [Oct.] 1937) and Karnaky all agree that certain strains of monilia are capable of producing in certain patients the clinical entity vaginal moniliasis. These workers fulfilled Koch's postulate. Moreover, there is good evidence that some women may be carriers without having the clinical state develop, while in others moniliasis may

develop when the environment is favorable. Thus, this organism is an opportunist. So, until equally good evidence refuting these observations is forthcoming, these reports would seem to stand.

4. It is assumed that the authors made these vaginal cultures at or near term. Published reports of larger series of oral thrush and vaginal mycosis are in direct disagreement, indicating that with larger series the experimental errors are reduced appreciably. The authors offer no source for the contaminations. It is acknowledged that not all oral thrush is contracted from the mother's genital tract, yet it is well established that this is the most frequent source.

5. Why credit the lochial flow as a fungicidal agent when biopsy studies demonstrate a marked and rapid depletion of the glycogen-like material in the vaginal epithelium immediately after delivery (a state unassociated with vaginal mycosis). Early in studies by other workers it was stated that alkalinity of the lochial flow influenced the course of the mycosis, but now enough available data and confirmatory reports offer, if not establish, a more correct answer, namely a deficiency of nutritive materials. H. CLOSE HESSELTINE, M.D., Chicago.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

APPEARANCE OF THROAT IN INFLUENZA

To the Editor:—My associate, who has been practicing thirty years, claims to be able to diagnose grip, or influenza, by means of a pathognomonic throat sign, namely, the appearance of a sharply demarcated, kidney-shaped area of redness confined to the anterior pillars of the fauces with its convexity facing the last lower molar tooth. I have consulted the literature and other physicians on this subject, together with making my own observations, and am unable to confirm this sign, as such a redness appears apparently in many normal throats, especially in smokers. Also the physician claims to be able to prognosticate the course of the disease by means of the gradual fading of this circumscribed redness. He states also that this sign will appear in contacts before the onset of temperature elevation. The rest of the pharynx is allegedly not injected. Is there anything in the literature confirming or denying this sign?

M.D., New York.

ANSWER.—There is no convincing evidence to substantiate the idea that the sign described is pathognomonic of influenza. Most observers who have had an opportunity to study a large number of cases of influenza at a given time have recorded a diffuse redness of the pharynx, soft palate and faucial pillars. In addition there is observed a distinct swelling of the lymphoid follicles resembling discrete glistening dewdrop nodules on the uvula and soft palate. There is frequently a glazing of mucus over the posterior pharyngeal wall, with an enlargement of lymphoid follicles in this location as well. This general description has been termed characteristic, but to say that it is absolutely diagnostic would be exceeding the facts.

RIGOR MORTIS

To the Editor:—Kindly enlighten me regarding cadaveric rigidity. How soon does it set in? How long does it endure before floccidity occurs? What variations may be expected in warm weather outdoors? What variations may be expected in newborn infants exposed outdoors in warm weather?

M.D., Missouri.

ANSWER.—Ordinarily rigor mortis starts between three and six hours after death and develops first in the musculature of the head, face and jaws. It then extends to the upper extremities, the trunk and the lower extremities in sequence, and the process becomes complete in about two hours. Its disappearance occurs in from twenty-four to seventy-two hours or more and the progress of the disappearance is usually in the same regular sequence.

Rigor mortis is influenced by a number of conditions and in persons dying of convulsions or after excessive muscular exertion the rigidity appears quickly, often within an hour from the time of death. Generally in powerfully muscled persons

rigor develops slowly and is retained for a long time. In those with poorly developed musculature, as infants and emaciated persons, the rigidity appears rapidly and is lost rapidly. Heat accelerates the onset and speeds its dissolution. Cold also hastens the onset but tends to retard disappearance, so that the stiffness may be retained for days or even weeks. In such cases it may be necessary to distinguish rigor mortis from stiffness attributable to freezing of the body or to mummification.

In a newborn infant, rigor would ordinarily develop quickly and disappear rapidly. At times in these cases the rigor is fleeting and may be overlooked.

From these considerations it is evident that the different stages in the process can rarely be used as definite criteria in determining the time of death. However, if rigor is found only in the head, face and jaw muscles and the body is still warm, it is reasonable to estimate the postmortem interval as between three and six hours. If rigor is found in the torso and arms and not in the legs, death probably occurred less than twelve hours prior to its onset.

If the legs are stiff but not the torso and arms, it is probable that the person has been dead two or three days. In a body found stiff and cold no definite opinion can be expressed as to the postmortem interval. In any event, estimation of the time interval must be made with caution.

SPAS AND MINERAL WATERS

To the Editor:—Within the past few weeks I have had inquiries from patients as to the value of the spas of Europe and America. 1. Which are the most important ones? 2. What types of diseases do they seem to benefit? 3. Are the springs of America as beneficial as those of Europe? 4. Are all supervised by competent physicians? 5. Do they have dietary regimens, exercises, massages and the like in connection? 6. Where can I obtain information as to the exact chemical analysis of these waters? 7. About how many people frequent these places and what percentage derive some benefit? 8. Can these salts and waters be imported for use in the home? 9. Where can I get a copy of "Spas and Mineral Waters of Europe?" I do not know the names of the authors or publishers, but it was printed in 1896.

M.D., Minnesota.

ANSWER.—1. Important spas in the United States include Hot Springs, Va.; White Sulphur Springs, W. Va.; Hot Springs, Ark.; French Lick, Ind.; Mount Clemens, Mich.; Excelsior Springs, Mo.; Saratoga Spa, Saratoga Springs, N. Y.; Sharon Springs, N. Y.; Glen Springs, Watkins Glen, N. Y., and a number of others.

In Europe the spas in France include Vichy, Vittel, Aix-les-Bains, Royat and many others. In Germany, Baden-Baden, Wiesbaden, Bad Nauheim, Bad Ems, Carlsbad, Marienbad and Bad Gastein are prominent. In England, Bath, Buxton and Harrogate are important. In each country there are other places where spa therapy can be carried out to good advantage.

2. In general, the use of mineral waters and spa treatment is of some value in chronic disabling conditions, including those affecting the heart and circulation; rheumatic disorders; ailments of the stomach, intestinal tract, gallbladder and liver; nervous conditions; certain disorders of the skin, and some metabolic diseases. It is obvious that not every patient with any of these conditions is a proper subject for spa treatment. The most promising patient is one who does not require bed care, who may be treated as an ambulatory patient and who can take advantage of the many-sided program which is available in a well equipped spa; in fact, the regimen may be more important than the composition of the water.

3. Treatment with mineral waters has the same effect in the United States as in Europe.

4. Competent medical advice is available at practically all spas; the physician referring patients for treatment at a spa should place his patient in the care of one of these physicians, who will outline the program. In most places the spa physician is in private practice. In a few places he is associated with the spa organization.

5. Nearly all places have arrangements for dietary regulation, exercise and massage, the details of which should be outlined completely by the spa physician in charge of the patient's program.

6. "Mineral Waters of the United States and American Spas," by Dr. William Edward Fitch (Philadelphia and New York, Lea & Febiger, 1927), gives the chemical analysis of many mineral waters.

In Europe each country has a publication listing the spas of the country, the nature of their waters and the provisions available for treatment. These may be obtained from their respective travel or publicity bureaus in the large cities such as New York.

7. There are no available statistics regarding the actual number of people taking treatment in the spas of the United States. It is estimated that each year from 40,000 to 50,000

patients take regular treatment at Hot Springs, Ark., and from 12,000 to 15,000 at the Saratoga Spa. These estimates indicate that many people take spa treatment in this country. It is impossible to give the exact percentage of those deriving benefit. Benefit from spa treatment occurs (1) in the specific medical ailment and (2) in the general state of health of the patient. One cannot neglect the psychotherapeutic value of a well organized program of treatment, which, with many patients, goes a long way in building up the morale.

8. Some mineral waters are bottled for home use and can be obtained through the distributing agency of the company handling the waters. The salts of the Carlsbad waters have been imported for years. It must be remembered that the extraction of salts from a mineral water gives a residue which many times cannot be completely dissolved when added to plain water. The artificial duplication of natural mineral waters has not been successful because they practically all contain, in small amounts, a certain number of mineral constituents which are not included in the artificial preparation.

9. There is no recent book in English which gives a general survey of mineral waters and spas. The following references deal particularly with certain phases of this important program:

1. Wallace, A. W.: The Modern Health Resort, *THE JOURNAL*, Aug. 8, 1936, p. 419.
2. Fantus, Bernard: Our Insufficiently Appreciated American Spas and Health Resorts, *THE JOURNAL*, Jan. 1, 1938, p. 40.
3. McClellan, W. S.: The Place of Carbon Dioxide Baths in the Treatment of Diseases of the Circulation, *Internat. Clin.* 1:199 (March) 1937.
4. McClellan, W. S.: The Saratoga Spa: Its Place in the Treatment of Rheumatic Disorders, *Arch. Phys. Therapy* 18:408-473 (Aug.) 1937.
5. Kovacs, Richard: American Spas, *Hygeia* 17:207 (March) 1939.

Mineral waters and spa therapy, important as they are, represent only one method of treatment available to the physician, and use of these facilities should be made in conjunction with other methods of treatment such as drugs, dietary regulation and physical measures. Details regarding the chemical and physical properties of the mineral water, the type of accommodations, the cost of treatments and the medical supervision may be obtained by writing to the administration of any of the spas. "Spas and Mineral Waters of Europe" by H. Weber and F. P. Weber was published in London by Smith, Elder and Company in 1896 and 1898. The book is out of print, and no record has been found of the publishing house as being active today.

OPTI-MED AND OBESITY

To the Editor:—The enclosed abstract and order blank was sent me through the mails from Germany, apparently introducing this new proprietary product called "Opti-Med." Inquiry and a brief search fail to reveal the character of the ingredients. Quite obviously, the reliance on some preparation to hinder or retard intestinal absorption to lose weight would seem hazardous. I should greatly appreciate information concerning the preparation with special reference to the mode of action, dangers and reason—if any—for the inclusion of the ingredients.

M.D., New York.

ANSWER.—Opti-Med has not been considered by the Council on Pharmacy and Chemistry and is apparently another name for the obesity treatment marketed by the firm of Dr. Rudolf Reiss of Berlin, under the name "Adiposettes." The American distributor is H. H. Beisner, New York.

The advertising for Opti-Med tablets which has recently been sent to American physicians directly from Dr. Rudolf Reiss (Chemical Works), Berlin, includes no adequate statement of the composition of the tablets. In lieu of a quantitative declaration of the ingredients in simple terminology the German manufacturer offers the following statement, which is inadequate because no quantities are given and because two of the ingredients are described in terms which apparently are designed to conceal rather than reveal their identity: "Opti-Med contains: Extract. fuc. vesic., extract. frangulae, lecithin, tritetraboryl-bis-propanetriolester, bis-oxyphenylphthalide."

In Martindale's "Extra Pharmacopoeia" (London, The Pharmaceutical Press, 1936) "Adiposettes" are described as follows: "Ext. fuc. vesic. 5.9%, Ext. frangul. 8%, lecithin 1%, tetraboryl-bis-propan-triolester 30%, triphenylcarbinol-o-carbonic acid glycolate 10%."

From the foregoing statements it appears that the anti-fat tablets of Dr. Rudolf Reiss (Chemical Works) contain extract of fucus vesiculosus (bladderwrack), extract of frangula (buckthorn bark), lecithin, a derivative of a boric acid glycerin ester, and a substance which is either phenolphthalein or a closely related product. This combination of purgative drugs together with other agents not infrequently found in anti-fat nostrums is offered to physicians as "a valuable preparation, free from any undesirable by-effects," one "which effectively reduces body weight without harm to your patient." It is also claimed that

"Whilst a suitable diet (and no alcohol), is—as you know—of help, European doctors have reported successful treatments of many cases, *without* changing the mode of living of their patients."

Since the boric acid glycerin ester is stated to be the "specifically acting" constituent that increases the oxidation of fat and decreases the assimilation of food in the intestine, it may be well to recall the following excerpt from Dr. F. Zernik's article, "New Pharmaceuticals in Germany," in the *Manufacturing Chemist* of June 1935:

"Of late the medicinal products industry has devoted increasing attention to slimming preparations. After numerous official warnings or prohibitions had been issued against the dangerous nature of dinitrophenol or its derivatives, interest has been diverted towards boric acid-containing preparations. Popularity was acquired in this connection by compounds of boric acid with urea, as well as sodium compounds of boric acid. A representative of this group is adiposettes (Dr. Rudolf Reiss, Berlin), dragées combining purgatives with seaweed extract and a boric acid glyceryl ester. The German Office of Health has published a warning, pointing out that boric acid and borax, whenever administered in quantities greater than a fraction of a gram, do not belong to those preparations entirely free from undesirable action upon human beings and that, therefore, the consumption of boric acid-containing preparations for slimming purposes without medical supervision may eventually be injurious to the health. Recently the use of boric acid slimming preparations has been completely prohibited in Denmark, probably for the reason stated above."

ATTACKS OF EPIGASTRIC PAIN WITH DEFECATION

To the Editor:—A white woman aged 53 complains of recurrent attacks of epigastric pain of severe intensity. The onset of the attacks occurred approximately two years ago, during which time they have been irregular as to frequency, sometimes not occurring for a period of months and again occurring two or three times in one week. The duration is from two to five hours. The patient's first premonition of an ensuing attack is a feeling of abdominal fullness with a desire to move the bowels. The attack comes on with severe pain; there is no abdominal tenderness and no elevation of temperature; at times there does exist a slight vertigo on arising, and often there is a chill after the pain subsides without any elevation of temperature after the chill. After the attack has passed, the patient feels no ill effects whatever except fatigue and is able to be up and about without any abdominal discomfort or gastrointestinal disturbances. There is no nausea during the attack or after. The bowels are moved two or three times during an attack but afford no relief. Various types of medication have been attempted to relieve the attack without any results. However, whisky on one occasion produced sleep but since that time has been unsuccessful. Morphine, both by mouth and hypodermically, has produced no effect on the patient. The patient gives a history of having had gall-bladder colic five years ago, the nature of these attacks being entirely different from the present ones, and the diagnosis of attacks of gallstone colic was questioned at that time. The patient has developed a fear of future attacks and more or less anticipates them continuously, with a resulting depression and melancholia. The attacks, except in two instances, have occurred just before she retires and on two occasions have awakened the patient from sleep. During an attack, physical manifestations such as elevation of temperature and tenderness are essentially negative. Following a series of attacks the patient guards her diet, not because of qualitative food dyspepsia but because of a fear of another attack, and consequently loses considerable weight. However, if the attacks do not come as she anticipates she increases her diet with no ill effects and gains weight, leaving her in a happy frame of mind. The patient normally suffers from constipation but keeps the bowels open with a mild laxative, and there is definitely no history of constipation preceding an attack. I would be interested in having your opinion as to diagnosis and treatment.

M.D., Pennsylvania.

ANSWER.—At this woman's age one would think first of definite organic disease involving perhaps the small bowel. The fact that these attacks have persisted for two years, during which time the patient hasn't come to any bad end, would tend to rule out a neoplasm or any lesion obstructing the bowel. The tendency to gain in weight is also encouraging. Lesions of the small bowel usually force the patient to operation within six months after the symptoms begin. The desire to move the bowels with attacks suggests something irritating the bowel. Apparently there are no symptoms of intestinal obstruction. The shortness of the attacks and the lack of physical indications suggest more a functional disturbance, such as is seen in rare cases of abdominal migraine. Sometimes at the menopause a typical migraine will change and produce attacks somewhat like those described. The absence of nausea speaks against the presence of migraine or of a lesion in the bowel. The fact that morphine does not work is much in favor of a functional trouble rather than an organic one.

Something like this picture can be seen in nervous persons after emotional debauches. The commonest cause, of course, of severe abdominal pain in a woman of this age would be gallstones. Gallstone attacks, however, should have responded to morphine. Naturally one would want to examine the gall-bladder with x-rays to see whether it is functioning and whether it contains stones. It would be helpful to see whether after an attack the serum bilirubin goes up. The fact that attacks have awakened the patient from sleep indicates organic disease.

A remote possibility is that the patient may be responding allergically to some food; allergy is not so likely to begin at the age of 51. It might be well, however, to have the patient keep a record to see whether attacks follow the eating of any particular food.

It would be helpful in a case such as this to watch a barium sulfate meal as it passes down the small intestine to make sure that there is no obstruction anywhere. One possibility is that the attacks are due to an internal hernia, but in this case the patient would probably have come to grief before now.

In cases such as this it is generally wise not to explore the abdomen unless some definite indication is found for it. It is presumed that the knee jerks are present and that the Wasserman reaction is negative. The attacks do not much suggest a "crisis." Another lesion that has to be ruled out is a small duodenal ulcer with perforation posteriorly. In such cases one can generally obtain a history of ulcer many years before. One might think also of pancreatic stones and perhaps arteriosclerotic changes in the mesenteric blood vessels. Such changes are common but generally silent. One would think of a lesion of the spinal cord, but this probably would have brought serious trouble in the course of two years.

STAINED LIPS FROM SMOKING

To the Editor:—Could you tell me why nicotine stain should collect on my lips while smoking? It is much heavier with cigarettes than with a pipe. The staining is so heavy it produces a dark brown discoloration on handkerchiefs, which wash with great difficulty. I smoked about three packs of cigarettes for a period of five years when one day I noticed on my lips a dark brown stain which would rub off easily. I tried a holder and then filters, without an iota of help. I changed to pipe smoking and the stain is greatly improved. Nevertheless, some still collect. I have absolutely no discomfort—never have cracked or chapped lips. Could you suggest any treatment?

M.D., New York.

ANSWER.—This experience seems unique. None of the smokers of cigarettes, dentists or physicians consulted have noted staining of the lips by cigarettes. Tobacco of any kind will produce a brown juice when chewed. This is not due to nicotine, which is a colorless liquid turning brown only on aging.

As the color rubs off easily one should not be too concerned. Perhaps smearing the lips with petrolatum or a wax pomade would be helpful. Paper handkerchiefs, easily obtained, would avoid the staining of linen.

SULFANILAMIDE FOR TYPHOID CARRIERS

To the Editor:—Kindly send references on the use of sulfanilamide for typhoid carriers. What is the present consensus as to its value in this connection?

M.D., Virginia.

ANSWER.—One reference has been found to the use of sulfanilamide in the control of the typhoid or paratyphoid carrier state. A. T. Bazin (*Canad. M. A. J.* 38:559 [June] 1938) reported that he had been able to eradicate paratyphoid bacilli from the bile of a carrier by intensive therapy with sulfanilamide. It would seem from the literature however that, since sulfanilamide has not been especially effective in the control of clinical typhoid and paratyphoid infections, its use in the carrier state would not be of great value unless one was dealing with urinary tract carriers. For this type of carrier sulfanilamide might be of some value because one can obtain high concentrations of the drug in the urine of treated persons provided adequate quantities of the drug are prescribed.

DILUTIONS FOR TUBERCULIN TESTING

To the Editor:—Each fall my associates and I do 1,500 tuberculin tests using two strengths of purified protein derivative. We could considerably reduce the cost of this procedure if we bought only a stronger dilution and made up the weaker dilutions ourselves. Will you please send us directions for making up the proper diluting fluid.

Edgar S. Krug, M.D., State College, Pa.

ANSWER.—Since the second dose is 250 times the strength of the first, the simplest way to achieve the desired first dose from a second strength tablet would be to dissolve a second strength tablet in 250 cc. instead of 1 cc. of the buffer solution. This would yield a solution containing 2,500 doses. Since this is probably greatly in excess of what would be used within the keeping limits of the diluted solution, a smaller quantity would be preferable. This can be prepared by making dilution in two stages: e. g., dissolve one second strength tablet in 1 cc. of buffer solution, withdraw exactly 0.1 cc. with a sterile calibrated syringe and add it to 24.9 cc. of sterile buffer, or salt, solution. Each 0.1 cc. of the resulting 25 cc. will furnish the required first dose.

Medical Examinations and Licensure

COMING EXAMINATIONS
STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 18-20. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: Basic Science. Tucson, Dec. 19. Sec., Dr. Robert L. Nugent, University of Arizona, Tucson.

ARKANSAS: Basic Science. Little Rock, Oct. 23. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. Medical (Regular). Little Rock, Nov. 9-10. Sec., Dr. D. L. Owens, Harrison. Medical (Eclectic). Little Rock, Nov. 9-10. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: If written examination. Sacramento, Oct. 16-19. Oral examination (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California). San Francisco, Nov. 15. Sec., Dr. Charles B. Pinkham, 430 State Office Bldg., Sacramento.

CONNECTICUT: Basic Science. New Haven, Oct. 14. Prerequisite to license examination. Address State Board of Healing Arts, 1895 Yale Station, New Haven. Medical (Regular). Examination. Hartford, Nov. 14-15. Endorsement. Hartford, Nov. 28. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. Medical (Homoeopathic). Derby, Nov. 14-15. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: Examination. Dover, July 9-11. Reciprocity. Dover, July 16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: Basic Science. Washington, Oct. 23-24. Medical. Washington, Nov. 13-14. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Jacksonville, Nov. 13-14. Sec., Dr. William M. Rowlett, Box 786, Tampa.

ILLINOIS: Chicago, Oct. 17-19. Acting Superintendent of Registration, Department of Registration and Education, Mr. Lucien A. File, Springfield.

INDIANA: Indianapolis, June 18-20. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

KANSAS: Topeka, Dec. 12-13. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: Louisville, Dec. 5-7. Sec., State Board of Health, Dr. A. T. McCormack, 620 S. Third St., Louisville.

MAINE: Portland, Nov. 14-15. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: Regular. Baltimore, Dec. 12-15. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. Homoeopathic. Baltimore, Dec. 12-13. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, Nov. 14-16. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MINNESOTA: Minneapolis, Oct. 17-19. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Reciprocity. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MISSOURI: Kansas City, Oct. 26-28. Sec., State Board of Health, Dr. Harry F. Parker, State Capitol Bldg., Jefferson City.

NEBRASKA: Lincoln, Nov. 24-25. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

NEVADA: If written examination and reciprocity with oral examination. Carson City, Nov. 6. Sec., Dr. John E. Worden, 311 W. Robinson St., Carson City.

NEW JERSEY: Trenton, Oct. 17-18. Sec., Dr. Earl S. Itallinger, 28 W. State St., Trenton.

NORTH CAROLINA: Reciprocity and Endorsement. Raleigh, Dec. 11. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 2-5. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: Columbus, Dec. 5-7. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: Basic Science. Oklahoma City, Nov. 6. Sec. of State, Hon. C. C. Childress, State Capitol, Oklahoma City. Medical. Oklahoma City, Dec. 13. Sec., Dr. James D. Osborn, Jr., Frederick.

OREGON: Basic Science. Portland, Oct. 28. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Philadelphia, January. Dir., Bureau of Professional Licensing, Dr. James A. Newpher, Department of Public Instruction, 358 Education Bldg., Harrisburg.

SOUTH CAROLINA: Columbia, Nov. 14. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Pierre, Jan. 16-17. Dir., Medical Licensure, Dr. G. J. Van Heuvelen, State Board of Health, Pierre.

TEXAS: Austin, Nov. 20-22. Sec., Dr. T. J. Crowe, 918-19-20 Mercantile Bldg., Dallas.

VERMONT: Burlington, Feb. 13-15. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 13. Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

WEST VIRGINIA: Fairmont, Nov. 6-8. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: Basic Science. Milwaukee, Dec. 2. Sec., Professor Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. Medical. Madison, Jan. 9-11. Sec., Dr. E. C. Murphy, 314 E. Grand Ave., Eau Claire.

Delaware July Report

Dr. Joseph S. McDaniel, secretary, Medical Council of Delaware, reports the written examination held at Dover, July 11-13, 1939. The examination covered ten subjects and included 100 questions. Seventy-five per cent in each subject was required to pass. Thirteen candidates were examined, eleven of whom passed and two failed. Three physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Georgetown University School of Medicine.....	(1938)		85
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1937)		80

School	FAILED	Year Grad.	Per Cent
Hahnemann Medical College and Hospital of Philadelphia.....	(1937) 77,	(1938)	78
Jefferson Medical College of Philadelphia.....	(1937) 78, 81,	(1938)	80, 81
Temple University School of Medicine.....	(1938)		79
University of Pennsylvania School of Medicine.....	(1937)		82, 83
School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
George Washington University School of Medicine....	(1933)		Maryland
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1924)		Maryland
New York Homoeopathic Medical College and Flower Hospital.....	(1916)		New York

Arizona July Report

Dr. J. H. Patterson, secretary, Arizona State Board of Medical Examiners, reports the written examination held at Phoenix, July 5-6, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Three candidates were examined, all of whom passed. Five physicians were licensed by reciprocity and one physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of California Medical School.....	(1937)		81.5
Louisiana State University Medical Center.....	(1938)		84.3
Baylor University College of Medicine.....	(1938)		83.7
School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
State University of Iowa College of Medicine.....	(1936)		Iowa
St. Louis University School of Medicine.....	(1936)		Missouri
Jefferson Medical College of Philadelphia.....	(1932)		Penna.
Vanderbilt University School of Medicine.....	(1927)		Tennessee
McGill University Faculty of Medicine.....	(1924)		California
School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Duke University School of Medicine.....	(1934)		N. B. M. Ex.

Georgia June Examination

Mr. R. C. Coleman, joint-secretary, State Examining Boards, reports the written examination held by the State Board of Medical Examiners at Atlanta and Augusta, June 7-8, 1939. The examination covered ten subjects and included 100 questions. An average of 80 per cent was required to pass. Seventy-eight candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1939)		82.5, 87.8
Emory University School of Medicine.....	(1938)		83.2, 88.2,
	(1939) 82, 83.5, 84.6, 84.8, 84.8, 84.9, 84.9, 84.9,		85.1, 85.2, 85.2, 85.3, 85.8, 85.9, 85.9, 86, 86.2, 86.2,
	86.4, 86.5, 86.6, 87.4, 87.9, 88, 88.1, 88.1, 88.5, 88.7,		88.8, 88.8, 89.5, 90, 90.4, 90.6, 90.7, 94.6
University of Georgia School of Medicine.....	(1939)		80.9,
	81.1, 81.5, 81.8, 82, 83.1, 83.4, 83.8, 83.9, 84, 84.2,		84.7, 84.8, 85, 85.5, 85.2, 85.2, 85.3, 85.3, 85.7, 86,
	86.1, 86.1, 86.3, 86.5, 86.9, 87.7, 87.8, 91.2		
Harvard Medical School.....	(1935)		85, 85.3
Columbia University College of Physicians and Surgeons.....	(1939)		90.3
Cornell University Medical College.....	(1937)		84.3
New York Medical College and Flower Hospital.....	(1937)		88.4
University of Oregon Medical School.....	(1937)		85.4
Deutsche Universität Medizinische Fakultät, Prag.....	(1911)		84.2

Twenty physicians were licensed by reciprocity and two physicians were licensed by endorsement from January 5 through July 6. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Northwestern University Medical School.....	(1927)		Missouri
University of Illinois College of.....			California
University of Louisville School of.....			Kentucky

Book Notices

The Structure and Composition of Foods. By Andrew L. Winton, Ph.D., and Kate Barber Winton, Ph.D. Volume IV: Sugar, Syrup, Honey, Tea, Coffee, Cocoa, Spices, Extracts, Yeast, Baking Powder. Cloth. Price, \$9. Pp. 580, with 134 illustrations. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Limited, 1939.

The present book completes this notable series of four volumes on foods. It includes four parts, or sections, on sugar, syrup and other saccharine products, on so-called alkaloidal products, on spices and extracts and other flavoring materials, and on leavening agents such as yeast and baking powders. There is also a chapter of addenda to volumes II and III of the series. It is in the sections on food adjuncts particularly that the value of the authors' method of presentation is apparent. There is presented not only the usual description of chemical composition but also a discussion of each subject from the botanic point of view, illustrated by numerous excellent drawings of cell structures. Many of the spices can be better identified by determination of the morphologic characteristics of material under examination than by chemical analysis. Although the botanic method of description and classification has been emphasized, the chemical presentation has not been neglected. The book is suitably indexed. It is the kind of book one may turn to with confidence to find information on inquiries such as: What is the composition of maple syrup from different parts of the country? What is caramel? What enzymes have been found in honey? What products have been found in coffee, tea and cocoa? What is the nature of oil of peppermint? What alkaloids have been found in pepper? What is the difference between paprika and pimiento? What are the constituents of bakers' yeast? How are baking powders classified? This volume is a fitting conclusion to the encyclopedic series. The set comprises a veritable mine of information about the structure and composition of foods and food adjuncts, written by experts who have had a lifetime of experience in the field.

Traité d'ophtalmologie. Publié sous les auspices de la Société française d'ophtalmologie. Par MM. F. Baillart, Ch. Coutela, E. Redslob, E. Vetter. René Onfray: Secrétaire général. Tome I: Histoire, embryologie, anatomie. Par MM. L. Cerise et al. Cloth. Pp. 1,042, with illustrations. Paris: Masson & Cie, 1939.

This is the first of an eight volume treatise on ophthalmology sponsored by the French Society of Ophthalmology with completion promised in less than a year. There are 103 collaborators from France, Belgium and Switzerland. A general table of the entire material to be covered is in the beginning of the first volume and an alphabetical index of all the volumes is promised for the end of the eighth volume. At the end of each chapter is a moderate sized but comprehensive bibliography embracing the modern literature in all languages. A rather interesting and useful novelty is the printing on each page of just where the bibliography pertaining to the subject matter of that page is to be found.

The three fairly modern compilations of ophthalmology are the Graefe-Saemisch Handbuch (which has taken forty years for completion), the Kurzes Handbuch der Ophthalmologie and the American Encyclopedia of Ophthalmology. The new French traité does not follow the pattern set by any of these but branches out boldly on a new path of its own. That path conforms to the advances of the recent decades, even though each collaborator has been allowed full sway to handle his subject matter as he has seen fit. If the clinical parts of the traité maintain the standards set by the first volume, the ophthalmologic world will have something new and valuable.

The first volume opens with an elaborate table of contents preceded by the names, titles and locations of the collaborators. Then comes a short and somewhat inadequate history of ophthalmology by Villard of Montpellier. The general development of the visual apparatus was written by Leplat of Liège, is well done, and has some original illustrations of embryos from the collection of the University of Liège. This is followed by a chapter on the embryology of the different parts of the ocular apparatus by Dejean of Montpellier. Although not lengthy, the material is well presented and well illustrated. A short chapter on comparative embryology and phylogenesis of the

visual apparatus by the same author follows. Then comes a long and detailed description of the anatomy and histology of the orbit and the ocular adnexa by Winckler of Strasbourg. This is well illustrated with many photographs of original dissections and diagrams of intra-orbital contents. This chapter is particularly good, for it contains much material that cannot be found elsewhere. The anatomy and histology of the lacrimal system and of the vascular system of the ocular apparatus was written by Jayle of Marsilles. The crowning section of the volume, however, is the chapter on the anatomy and histology of the eyeball by Redslob of Strasbourg. Every ophthalmologist, no matter how experienced, can read that with profit. Then follow the shorter chapters on the anatomy of the optic pathways by Lhermitte of Paris, the anatomy of the oculomotor nervous system by Van Gehuchten of Louvain, the anatomic pathways for ocular sensibility by Cerise and Thurel of Paris, the anatomy of the sympathetic and parasympathetic nervous system of the ocular apparatus by Tournay of Paris and comparative anatomy and physiology by Rochon-Duvigneaud of Paris. The last two and somewhat longer chapters on heredity and teratology are by Van Duyse of Ghent.

In a review of this character it is of course impossible even to try to evaluate each individual chapter. Suffice it to say that a high standard of excellence is maintained throughout the volume, which occupies a somewhat unique place in ophthalmic literature. The volume is printed on rather thin paper, according to our standards, and the type is somewhat fainter and smaller than we are accustomed to use. The illustrations are uniformly excellent, the majority being in black and white. However, the few colored illustrations give great promise for the volume that will cover diseases of the fundus. In producing this eight volume work the French Society of Ophthalmology is making a distinct contribution to modern ophthalmology. For all libraries and readers of French, this encyclopedia is a necessity.

You're the Doctor. By Victor Helser, M.D. Cloth. Price, \$2.50. Pp. 300. New York: W. W. Norton & Company, Inc., 1939.

This is a rambling, somewhat discursive, book on health which discusses many phases of the subject, few of them adequately and many of them superficially. Readers of *An American Doctor's Odyssey* will be disappointed. The book contains some interesting anecdotes based on the author's worldwide experience and travels but it lacks the vivid and interesting qualities of his odyssey.

On page 84 his first paragraph on vitamin C mentions the most concentrated source as paprika, but paprika cannot be used in significant amounts to make a real contribution of vitamin C to the diet, as can oranges, lemons, grapefruit, tomatoes and raw cabbage; he mentions only tomatoes specifically and singles out no fruits or vegetables as exceptionally good sources of vitamin C, except boiled potatoes.

On page 201, in a brief paragraph on hernia, he says "Operative cure is usually simple and recently, under certain conditions, some have been effected medically without aid of the surgeon by injecting irritating substances." This is misleading; the safety of injection methods depends on the careful selection of cases and the technic of a well qualified surgeon.

On page 250 he credits the supervision of small private hospitals to municipal health departments and makes no mention of the American Medical Association Council on Medical Education and Hospitals, the American College of Surgeons or the American Hospital Association; all these have contributed infinitely more to improvement of hospital standards in the United States than has any health department, except so far as a few of the larger municipalities may operate their own hospitals. Even these have been known to be unacceptable to professional agencies adhering to high standards.

On page 253 he says that outbreaks of measles can be suppressed quickly by injecting serum. Health officials seem to have overlooked the availability of a quick means of suppressing measles epidemics; the truth is, of course, that mortality has been curtailed by the use of convalescent serum but never has there been available an adequate supply of this preparation and never has any considerable epidemic been suppressed by this technic.

On page 261, after recounting how he procured the cooperation of many agencies in a proposed new health program for

Halifax, he says "Only after an hour and a half conference did the Halifax Medical Association agree." With reference to no other agency does the author use this implication of reluctance when, as a matter of fact, an hour and a half seems hardly a long conference if it results in the enlistment of cooperation for an entirely new health program for an important seaport like Halifax.

These statements are chosen at random in support of the reviewer's opinion that the book is poorly organized and unbalanced. It is of course an assemblage of essays written from time to time for a variety of publications.

A Cerebral Atlas Illustrating the Differences Between the Brains of Mentally Defective and Normal Individuals with a Social, Mental, and Neurological Record of 120 Defectives During Life. By Richard J. A. Berry, M.D., F.R.S.E., F.R.C.S.E., Director of Medical Services to the Incorporation of National Institutions for Persons Requiring Care and Control, Stoke Park Colony, Bristol. Cloth. Price, \$35. Pp. 425, with 441 illustrations. New York, Toronto & London: Oxford University Press, 1938.

The study conducted by Dr. Berry and his associates has consisted of the correlation of clinical observations with physiologic and anatomic evidence. He has compared the brains of idiots, imbeciles, moral defectives and feeble-minded persons with those of normal persons. He has compared them as to actual size by the brain product method, he has compared them as to weights of the right cerebral hemisphere and he has compared the planimeter cortical areas as determined on the flat by dioptrographic tracings. He has also compared as to morphologic changes grossly and microscopically the brains of feeble-minded persons with those of normal persons.

In determining the actual size of the brain by the brain product method, he multiplied the length by the breadth and the height of the brain by dioptrographic tracings and for practical purposes used the same measurements on the head and assumed that the proportion of brain size is about 66 per cent; that is, the brain is about two thirds the size of the head. In estimating the weight of the brain, the right cerebral hemisphere alone of both normal and defective persons is stripped, mounted in formaldehyde-saline solution and weighed after the removal of all superfluous fluid either inside or outside the brain. Surface areas of the brains of normal and feeble-minded persons were calculated by dioptrographic tracings. Comparisons of respective areas in normal and diseased brains were made to bring out the morphologic differences.

Dr. Berry's atlas is of incalculable value, since each series of photographs is accompanied by a thorough history and neurologic examination in the case prior to death of the patient, as well as computations as to the actual size of the brain product and the weight of the right cerebral hemisphere and cortical areas. The photographs in every instance illustrate the gross morphologic changes.

In summary the author states that, during its growth from birth to adult, the average brain increases in weight by roughly 1,000 Gm. According to Donaldson, it does so by an increase of its non-nervous constituents and by an enlargement of its nerve elements:

These latter changes are dependent on the increase in the mass of the cell body and cell outgrowth, especially the axons, and in the acquisition of the medullary sheath. Calculation shows that the absolute mass of the medullary substance is the chief source of increase in weight during this period. The weight increase in the nerve element proper is due to the enlargement of those cells which at birth are small, the addition of nerve cells being excluded since their formation ceased at birth.

The author further states that if, therefore, a defective brain is found to weigh less than a comparable normal brain—the two having been weighed under strictly similar conditions—to be appreciably smaller and to possess a corpus callosum (through which all medullated neopallial commissural axons must pass) smaller than normal, it is a reasonable inference that the brain is deficient in its number of fully developed and properly functioning cortical neurons and hence is incapable of achieving that type of mental reaction which distinguishes man from the animals. On the whole, the brains of idiots are 10 per cent smaller than the brains of normal persons:

The chief differences between defective brains and a normal one of the type described may be summarized briefly as follows. In a defective brain there is:

1. A considerable reduction in size and weight.
2. A tendency for the persistence in the convoluted pattern of certain prenatal development features.

3. A greater variation than occurs normally in the gyri and sulci bordering the central sulcus of Rolando—that is, in the important effector and receptor areas.

4. A lack of full development in the opercula, particularly in the frontal one, which frequently fails to cover the insula.

5. A diminution in the cortical amount of the triangular parietal area—that is, of the area concerned with the association of incoming impulses from the somesthetic, acoustic and visual areas.

6. On the medial surface the corpus callosum appears to be frequently diminished in size, notably the genu and splenium.

7. The visual areas exhibit more variation in pattern and extent.

8. Lastly, the sulci generally appear to be shallower in the defective brain than in the normal.

Hammberg, in his classic studies of normal and idiot brains, long ago pointed out that even comparatively small diminutions in the development of the cortical cells were sufficient to reduce the intelligence to moderate imbecility. Any of the variations just described as of frequent occurrence in the defective brain have a precisely similar effect.

The reviewing of this work has been exceedingly interesting and instructive. The author has presented comparisons of defective brains with those of the normal brain as no other author has done. The presentation of the clinical symptoms due to morphologic changes in the brain elucidates the problem of the mentally defective. The atlas not only is of value to the anatomist and physiologist but should be an excellent reference work for every neurologist and psychiatrist.

Alcoholics Anonymous: The Story of How More Than One Hundred Men Have Recovered from Alcoholism. Cloth. Price, \$3.50. Pp. 400. New York: Works Publishing Company, 1939.

The seriousness of the psychiatric and social problem represented by addiction to alcohol is generally underestimated by those not intimately familiar with the tragedies in the families of victims or the resistance addicts offer to any effective treatment. Many psychiatrists regard addiction to alcohol as having a more pessimistic prognosis than schizophrenia. For many years the public was beguiled into believing that short courses of enforced abstinence and catharsis in "institutes" and "rest homes" would do the trick, and now that the failure of such temporizing has become common knowledge, a considerable number of other forms of quack treatment have sprung up. The book under review is a curious combination of organizing propaganda and religious exhortation. It is in no sense a scientific book, although it is introduced by a letter from a physician who claims to know some of the anonymous contributors who have been "cured" of addiction to alcohol and have joined together in an organization which would save other addicts by a kind of religious conversion. The book contains instructions as to how to intrigue the alcoholic addict into the acceptance of divine guidance in place of alcohol in terms strongly reminiscent of Dale Carnegie and the adherents of the Buchman ("Oxford") movement. The one valid thing in the book is the recognition of the seriousness of addiction to alcohol. Other than this, the book has no scientific merit or interest.

Milk Supplies and Their Control in American Urban Communities of Over 1,000 Population in 1936. By A. W. Fuchs, Senior Sanitary Engineer, and L. C. Frank, Senior Sanitary Engineer. From the Division of Public Health Methods, National Institute of Health. Prepared by direction of the Surgeon General. U. S. Treasury Department, Public Health Service. Public Health Bulletin No. 245. Paper. Price, 10 cents. Pp. 70. Washington, D. C.: Supt. of Doc., Government Printing Office, 1939.

This pamphlet provides the results of a study conducted by the U. S. Public Health Service on the production and consumption of fluid market milk, the volume and price of various grades of milk sold, the legal requirements and the extent of both pasteurization of milk and of the testing of milk cows for tuberculosis or infectious abortion, state and local milk control organization and personnel, and the inspection, sampling and bacterial quality of local milk supplies. The information which forms the basis of the report was secured by means of the questionnaire method and by correspondence, and there was made available information from more than 2,500 municipalities. It was found that nearly 75 per cent of the market milk in the municipalities studied was pasteurized and that 99.4 per cent was from tuberculin tested herds. It is pointed out that since 1923 there have been phenomenal progress in abortion testing in cattle, extensive progress in tuberculin testing and considerable progress in pasteurization. It is interesting to note from this survey that the daily per capita consumption for the entire country is estimated to be 0.66 pint of fluid market milk, 0.035 pint of cream and 0.031 pint of buttermilk, or a total of 0.73

pint. The total milk consumption was lowest in the Southern states and highest in New England. It is estimated that 36 per cent of the municipalities had a milk ordinance. Control of milk sanitation work was a function of the health department in twenty-two states, of the department of agriculture in twelve, jointly of health and agricultural departments in ten, and of some other agency in four. Some degree of local milk control was exercised in about one third of all municipalities. Milk supplies for the larger cities apparently are subjected to greater control than those of smaller municipalities. The information provided by this pamphlet should be valuable to all who are interested in statistics on the sanitation and consumption of fluid milk.

Electrocardiographie expérimentale: Application à la physio-pathologie du cœur, dualité du cœur, arythmies. Par le Docteur E. de Somer, professeur de pathologie générale à l'Université de Gand. Préface du Prof. Dr. Wennebaech. Paper. Pp. 142, with 122 illustrations. Paris: Masson & Cie, 1938.

In this brochure the author presents data on which he attempts to outline his ideas regarding the genesis of the electrocardiogram. There is little reference to the literature, the presentation is polemic, the views expressed are unorthodox, the evidence is unconvincing and the method of recording the electrocardiogram is unconventional. The spacing of the booklet into three separate parts containing respectively the text, the illustrations and the legends makes it extremely difficult to follow the abstruse presentation. Apparently the author is convinced of the dualistic theory of the origin of the heart beat, namely that there is one pacemaker for the auricles and another for the ventricles. This view has cropped up before and will probably appear again, but it has few advocates, and none apparently among the leading students of this subject.

Annual Review of Biochemistry. James Murray Luck, Editor. James H. C. Smith, Associate Editor. Volume VIII. Cloth. Price, \$5. Pp. 676. Stanford University P. O., California: Annual Reviews, Inc., 1939.

The eighth volume of these now indispensable reviews of annual advances in biochemistry is the first since the establishment of the companion volume known as the Annual Review of Physiology. It is the conviction of the editorial board that the publication of two sets of reviews will considerably ease the trials of the authors. To the present commentator it seems to be a mistake to separate two closely allied subjects such as biochemistry and physiology, and one criticism of the articles in the present volume is that the physiologic aspects are too often omitted. Perhaps this is necessary, but it is unfortunate to establish any line of demarcation when none exists. The difficulties presented to the reader because of emphasis on chemistry may be exemplified perhaps by the following sentence, which appears in an authoritative review of the alkaloids: "The alkaline retronectine, the basic fragment from the hydrolysis of senecionine, retrosine, jacobine, squalidine, trichodesmine and seneciophylline, is converted by hydrogenation to retronectanol, $C_{15}H_{25}NO$."

The subjects in the present volume include biologic oxidations and reductions, proteolytic enzymes, nonproteolytic enzymes, polysaccharides and lignin, x-ray studies of the structure of compounds of biologic interest, the chemistry of the acyclic constituents of natural fats and oils, the chemistry of proteins and amino acids, the chemistry and metabolism of the compounds of sulfur, carbohydrate metabolism, lipid metabolism, metabolism of proteins and amino acids, mineral metabolism (calcium, magnesium and phosphorus), hormones, choline as a dietary factor, the water-soluble vitamins, the fat-soluble vitamins, metabolism of brain and nerve, the alkaloids, chemical aspects of photosynthesis, mineral nutrition of plants, growth hormones in the higher plants, animal poisons, ruminant nutrition, immunochemistry and the biochemistry of yeast. There is an author index and a subject index.

It is apparent from the list that some topics are so broad that much more space should be provided for their appropriate presentation. There is still too much mere cataloguing of papers without discussion or even mention of the results obtained. Thus in a discussion of molecular weight determinations of proteins there appears the sentence "Sumner, Galen and Eriksson-Quensel (1, 2, 3) studied the crystalline proteins, urease, canavalin, concanavalin A, and concanavalin B, from

the jack bean." The only way the reader can find out what values were found is to refer to the papers cited as numbers 1, 2 and 3. There is almost a page devoted to the discussion of molecular weight determination of proteins, and, although some values are recorded, it would be much more satisfactory to the reader if all the values were listed in a table. There are excellent tables of coenzyme specificity of dehydrogenases and tables of utilization of amino acid derivatives for growth.

Ernährungslehre: Grundlagen und Anwendung. Bearbeitet von B. Bleyer et al. Herausgegeben von Professor Dr. Wilhelm Stepp, Direktor der 1. Medizinischen Klinik der Universität München. Cloth. Price, 36 marks. Pp. 622, with 34 illustrations. Berlin: Julius Springer, 1939.

This is a modern textbook on nutrition written in German by seventeen contributors in addition to the editor. It is interesting to note the many references to American work as compared with the relatively few citations in some of the standard German textbooks of twenty or thirty years ago. In the discussion of energy requirements the work of F. G. Benedict, Du Bois and Boothby and their collaborators is discussed at length. The recent work of W. C. Rose, Brand, Lewis, du Vigneaud and others on the nutritional significance of the amino acids, including the recent work on the homologues of cystine, is presented. The expression "protective food" has been introduced into the German language as "schutzzstoffe." Discussion of some subjects, such as mineral metabolism, is brief, as is necessary perhaps because of the nature of the book. The chemistry of the vitamins is presented fully but briefly. Each chapter contains a selected bibliography. The references presented in the discussion of nicotinic acid and pellagra are not the most important papers. An interesting chapter by Schittenhelm discusses undernutrition and overnutrition and the "mehlnährschaden" of Czerny and Keller. The subjects in the section on avitaminosis and hypovitaminosis are well presented. The final section is an interesting discussion of nutrition as a public health problem, in which evidence regarding the requirements of different peoples is gathered together and discussed in the light of current information.

Principles of Healthful Living. By Edgar F. Vnn Buskirk, Ph.D., Professor of Hygiene and Health Education, Stephens College. Edited by Wilson G. Smille, M.D., Professor of Public Health, Cornell University Medical College. Cloth. Price, \$3. Pp. 386, with illustrations. New York: Dial Press, 1938.

This is a good textbook on hygiene at the college level. It is also a good reference book for the home, assuming that the education of the family is of high school level or above. It is not sufficiently appealing in style or treatment for the more or less casual reading of those who are mildly interested but not seriously concerned in making a study of health and hygiene. It deals in a comprehensive manner with the structure and functions of the body and its environment, placing a highly desirable emphasis on preventive medicine and at the time giving introductory information with relation to the principal diseases which afflict man. It does not encourage self medication but encourages what the author calls "reflective thinking" as a means of evaluating advertising claims with relation to health and attempts to develop a critical attitude toward such claims without at the same time discrediting honest commercial promotion. It should make a good basis for any course in hygiene and healthful living or for collateral reading and reference. In the critical sections relating to diet, the use of narcotics and stimulants, personality development and mental hygiene—in short, those places where faddism might easily have crept in—it is eminently sound. The book is attractively printed, with many simple and clear diagrams illustrating the anatomic structures, and is embellished with numerous photographs of excellent quality, sharply reproduced and intelligently employed. It has a good bibliography and an excellent index.

A banana: Fruto de todo o ano alimento-medicamento. Pelo Dr. Vleente Henriques de Gouveia. Resumée en français. Paper. Pp. 75, with 18 illustrations. Funchal, Portugal: The Author, 1938.

This is a discussion in Portuguese, with a French summary, about the composition and nutritional value of the banana. Unfortunately no references are provided to the original literature and the monograph itself presents no new facts.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Corporations: Group Health Association, Inc., Held Not Illegally Engaged in the Corporate Practice of Medicine or in the Insurance Business.—Group Health Association, a corporation not for profit, was organized under the laws of the District of Columbia providing for corporations for "benevolent, charitable, educational, literary, musical, scientific, religious, or missionary purposes, including societies formed for mutual improvement, or for the promotion of the arts." It undertook to provide medical and hospital services to its members and their dependents on a monthly prepayment basis. According to the published report, its membership is "limited to employees of the government in certain of the administrative branches." It entered into a contract with the Home Owners Loan Corporation whereby the latter agreed to pay \$40,000 in consideration of the association's providing for two years from Nov. 1, 1937, "substantially complete medical and hospital service to such employees of the Home Owners Loan Corporation as care to join it on a reasonable monthly payment basis." The United States District Attorney for the District of Columbia, claiming that the association was illegally engaged in the practice of medicine in violation of the Healing Arts Practice Act, notified the association that unless it suspended immediately its activities he would file a bill for an injunction or institute proceedings for the involuntary dissolution of the corporation. The Superintendent of Insurance for the District of Columbia contended that the association was engaged in the business of insurance in violation of the insurance laws of the District of Columbia. The association thereupon filed a bill of complaint in the district court of the United States for the District of Columbia against the district attorney and the superintendent of insurance. The defendants moved that the bill of complaint be dismissed.

Group Health Association, said the district court, was not practicing medicine in the sense that it itself prescribed for the sick. It was the contention of the association that it entered into contracts only with duly licensed physicians who themselves attended its members and if necessary prescribed for them. The court could see no reason why an individual or a group of individuals may not contract with a physician, or a group of physicians, for medical services for a stipulated period at a fixed compensation without violating the Healing Arts Practice Act. It seemed to the court that such a group of individuals might incorporate themselves for their own mutual benefit for the same purpose and that such a corporation, not for profit but for the mutual benefit of its members, would not be engaged in the practice of medicine or would not be holding itself out as doing so. While a corporation can act only through its agents and employees, the physicians with whom Group Health Association contracted to render medical services were, in the opinion of the court, independent contractors, for the association "does not in any way undertake to control the manner in which they attend or prescribe for their patients."

While the court expressed itself as having more difficulty with the contract between the association and the Home Owners Loan Corporation, it concluded that the medical and hospital services which the association agreed to furnish to the members of that corporation were substantially the same as those furnished to its own members. No profit was to be made for the association or its members.

The purpose of the Healing Arts Practice Act, the court continued, was to protect the public from quacks, the ignorant and incompetent. The activities of the association in no way tended to commercialize the practice of medicine, as the court viewed them; the association was not in the business of making money by furnishing medical services to any one who might come along. The court did not believe that the cases bearing on the right of a corporation to practice law were

closely analogous, "they being based on the common law and governed by the courts independently of any statute." For the reasons stated, the court held that the activities of the association did not constitute a violation of the Healing Arts Practice Act.

The contention of the superintendent of insurance that the association was unlawfully engaged in the business of insurance was based on the following provision of the insurance laws of the District of Columbia:

Every corporation . . . transacting business in the District of Columbia, which collects premiums, dues, or assessments . . . and which provides for the payment of indemnity on account of sickness or accident, or a benefit in case of death, shall be known as "health, accident, and life insurance companies or associations."

This provision, the court pointed out, does not include all "insurance" companies but only those which provide for the "payment of indemnity on account of sickness"; it does not include necessarily contracts "to indemnify," but is limited to those which provide for the "payment" of indemnity. The word "payment," the court continued, as ordinarily used means the payment of money, and the court could find no reason to believe that the word "is used in a different sense in the statute or that it is equivalent to 'indemnity.'" In the opinion of the court, the association was not engaged in the business of insurance within the meaning of the quoted provision of the law.

Accordingly, the district court overruled the motion to dismiss the bill of complaint.—*Group Health Ass'n v. Moor et al.*, 24 F. Supp. 445.

Malpractice: Volkmann's Paralysis Allegedly Resulting from Improper Application of Plaster of Paris Cast.

—Dewey Dark Jr., a boy aged 6 years, suffered greenstick fractures of both the ulna and the radius of the left arm on Thursday, March 4, 1937. Dr. Brown, a local physician, was called in but, since in his opinion it was necessary to "x-ray" the arm before administering any treatment, the child was taken to Dr. McAdams in a neighboring town. Dr. McAdams, after studying roentgenograms, reduced the fractures and applied a plaster of paris cast "next to the flesh," bending the elbow just before the cast hardened, which caused the cast to wrinkle at the elbow. The following day the arm began to swell, but Dr. Brown did not believe that the cast needed loosening. Saturday and Sunday nights Dr. Brown administered hypodermics and on Sunday loosened the bandage. When the child was taken back to Dr. McAdams on Monday the physician removed the dressing and drained and sterilized blisters which had formed on the top of the arm and on the hand. According to his testimony, at that time the pulse was good, there was no blueness in the fingers and the child could move his hand. The father testified, however, that at that time "inside the elbow it was black." Although the physician urged the father to hospitalize the child, the father failed to do so for two more days, in the meantime bringing the child to Dr. McAdams each day. The child was hospitalized Wednesday, the 10th, at which time he had a temperature of 103 F. Dr. McAdams removed the splint and the dressing and elevated the arm on a pillow. While the child was in the hospital, according to Dr. McAdams, the "temperature went down to practically normal, swelling was much better, the blisters looked better, he had a good pulse, and movement in his wrist and fingers" and he was free of pain. Over Dr. McAdams's objections the father removed the child from the hospital on March 12 and dismissed Dr. McAdams from the case, informing the physician that "he could get the boy attended to nearer home," mentioning a Dr. Cooper and saying nothing concerning Dr. Brown. Consequently Dr. McAdams gave Dr. Brown no instructions for treatment. Apparently, however, the father placed the child under Dr. Brown's care from then until March 22, when he was taken to the Dr. Cooper just referred to. When Dr. Cooper came into the case he found that the arm was swollen twice the normal size, the child had a high temperature, there was "no circulation" and the tissue was sloughing off in a spot about 2 inches long by 1½ inches wide. May 16, on Dr. Cooper's advice, the child was taken to Dr. Speed, a bone specialist in Memphis. Roentgenograms, Dr. Speed

testified, while showing a fracture of both bones of the forearm, destruction of one bone, osteomyelitis of this bone and to a certain extent other bones, showed excellent apposition of the bones at the points of fracture. Apparently Volkmann's paralysis had developed, the fingers had become stiff and the arm was useless, and subsequent procedures by the specialist were fruitless.

The father and the child subsequently sued Dr. Brown and Dr. McAdams for malpractice. The substance of their complaint was that "there was a want of skill on the part of McAdams and Brown, who acted jointly in applying the treatment—that the cast was applied too tightly, and when it was bent to accommodate the arm in a sling, wrinkles formed in the interior of the cast and, when it set or hardened, these wrinkles bruised the flesh when swelling occurred—a condition brought about through failure of the physicians to place yielding or resilient material between the flesh and the cast." From a judgment for the plaintiffs the defendants appealed to the Supreme Court of Arkansas.

The determining questions, as the Supreme Court viewed the controversy, were whether or not the cast was applied too tightly and whether or not it was good medical practice to place the cast in contact with the skin. From the fact, said the Supreme Court, that wrinkles did form in the cast at or near the elbow, it cannot be concluded that the infection complained of was caused thereby, and the evidence adduced justifies no such conclusion. Dr. Speed testified that the disability of the child was due to Volkmann's paralysis, which can result from a number of different causes: It might be the result of a direct injury to the blood vessels of the arm when the blood supply is cut off to the muscles; it might be due to hemorrhage or swelling within the fasciae covering of the arm, or it might be due to stricture due to splinting or pressure. He was unable to tell the original cause of the trouble but, in view of the testimony with regard to the circulatory condition—the presence of radial pulse, which indicates that blood is being supplied to the parts, and the movement of the fingers—he believed that when the child left the hospital on March 12 "there had been no serious or permanent interference, and with proper care from then on the condition should have improved, and the patient should have recovered." Dr. McAdams, in his opinion, handled the case well "throughout the treatment of the fracture, both regarding the x-raying of it, the reduction of the fracture, the apposition of the bones, the type of immobilization which was used, and the instructions which were given with regard to the kind of precautions necessary." Dr. Speed saw no objection "if the arm is almost straight to bringing it to right angle position after the splint is applied."

Six other expert witnesses, called on behalf of the plaintiffs, testified that the methods Dr. McAdams used were proper. Dr. Govar, another physician witness called by the plaintiffs, testified that it was optional with the physician whether splints or a cast be used to accomplish immobilization but that he wouldn't deem it advisable to place plaster of paris casts against the skin because "if a person is hairy the hair will join the cast, and if the skin is tender you may get a burn." No physician, said the court, testified for the plaintiffs that direct application of the cast to the skin would be improper from a professional standpoint. Dr. Govar's aversion to plaster of paris was based on the possibility that hairs on the arm might become attached to the cast "and if the skin is tender you may get a burn." There is no testimony in the record that the blisters caused infection or that the deep-seated malady was produced by plaster of paris burns, and Dr. Speed testified that direct application was generally approved. There is no testimony in the record to show that the cast was too tight when first applied. There is testimony that within a short time swelling occurred and that proper treatment probably would have been to loosen the tension. Dr. McAdams cannot be charged with such failure for he had no opportunity to act. The plaintiffs' entire case is predicated on the physician defendants' negligence and want of skill when the operation was performed.

Our conclusion, continued the court, is that the plaintiffs failed to support their allegations with substantial evidence. This is a case in which a layman took chances and experi-

enced misfortune of a tragic nature. If the doctrine *res ipsa loquitur* applied, the judgments might be sustained. But it does not. Medicine and surgery are inexact sciences, and physicians are not guarantors of results. Our view is that permanent injuries to the child were occasioned by the father's own negligence or error of judgment in not leaving the patient with Dr. McAdams when it became apparent that infection had developed.

The judgments in favor of the plaintiffs were reversed and the causes were dismissed.—*Brown et al. v. Dark (Ark.)*, 119 S. W. (2d) 529.

Compensation of Physicians: Liability of Third Person for Medical Fees.—Aileen Yaffe was injured while riding in the automobile of one William Yaffe. After the accident William sent her to a hospital in an ambulance and telephoned the plaintiff, a physician, and employed him to treat her. The plaintiff rendered medical services to the patient for four and one-half months. About two and one-half months after the accident Simon Yaffe, the stepfather of the patient and the father of William, visited the patient at the hospital and at that time had an interview with the plaintiff. The plaintiff claimed that Simon requested him to continue his services and told him to endeavor to get William to pay as much of the bill as he could but that he, Simon, and his wife would be responsible for the bill. Simon, his bookkeeper and his wife, who were present at the interview with the plaintiff, denied that he had made any such agreement. The plaintiff then brought suit against Simon, William and Aileen, the defendants, for \$2,750 as payment for his services. As a defense, Simon pleaded that the alleged contract was void under the statute of frauds because it was not in writing. From a judgment in favor of the plaintiff against all the defendants, Simon appealed to the Supreme Court of Arkansas.

The evidence, said the Supreme Court, showed that Simon merely promised the plaintiff that he would take care of the bill if William did not. The undertaking on the part of Simon, therefore, was collateral and not original. It was an undertaking on his part to pay the debt of another if the original debtor failed to pay the same. In the judgment of the court, therefore, the undertaking was within the statute of frauds and, because it was not in writing, was void. Accordingly, the Supreme Court reversed the judgment as to Simon and dismissed the cause as to him.—*Yaffe v. Pickett (Ark.)*, 121 S. W. (2d) 93.

COMING MEETINGS

- American Academy of Pediatrics, Cincinnati, November 16-18. Dr. Clifford G. Grulee, 636 Church Street, Evanston, Ill., Secretary.
- American College of Surgeons, Philadelphia, Oct. 16-20. Dr. Frederic A. Besley, 40 East Erie St., Chicago, Secretary.
- American Public Health Association, Pittsburgh, Oct. 17-20. Dr. Reginald M. Atwater, 50 West 50th St., New York, Executive Secretary.
- American Society of Tropical Medicine, Memphis, Tenn., Nov. 21-24. Dr. E. Harold Hinman, Wilson Dam, Ala., Secretary.
- Association of American Medical Colleges, Cincinnati, Oct. 23-25. Dr. Fred C. Zapffe, 5 South Wabash Ave., Chicago, Secretary.
- Central Association of Obstetricians and Gynecologists, Kansas City, Mo., Nov. 2-4. Dr. W. F. Mengert, University Hospitals, Iowa City, Secretary.
- Central Society for Clinical Research, Chicago, Nov. 3-4. Dr. L. D. Thompson, 4932 Maryland Ave., St. Louis, Secretary.
- Gulf Coast Clinical Society, Mobile, Ala., Oct. 26-27. Dr. Clyde C. Rouse, 56 St. Joseph St., Mobile, Ala., Secretary.
- International Society of Medical Health Officers, Pittsburgh, October 16. Dr. Leon Banov, 12 Mill Street, Charleston, S. C., Secretary.
- Inter-State Postgraduate Medical Association of North America, Chicago, Oct. 30-Nov. 3. Dr. W. B. Peck, 27 East Stephenson St., Freeport, Ill., Managing Director.
- National Society for the Prevention of Blindness, New York, Oct. 26-28. Mr. Lewis H. Carris, 50 West 50th St., New York, General Director.
- New York State Association of Public Health Laboratories, Albany, Nov. 3. Miss Mary B. Kirkbride, New Scotland Ave., Albany, Secretary.
- Omaha Mid-West Clinical Society, Omaha, Oct. 23-27. Dr. J. D. McCarthy, 107 S. 17th St., Omaha, Secretary.
- Pacific Coast Society of Obstetrics and Gynecology, Portland, Ore., Nov. 8-11. Dr. T. Floyd Bell, 400 29th St., Oakland, Calif., Secretary.
- Southern Medical Association, Memphis, Tenn., Nov. 21-24. Mr. C. P. Loran, Empire Bldg., Birmingham, Ala., Secretary.
- Southern Surgical Association, Augusta, Ga., Dec. 5-7. Dr. E. Altz Ochsner, 1430 Tulane Ave., New Orleans, Secretary.
- Tri-State Medical Society of Texas, Louisiana and Arkansas, Marshall, Texas, Nov. 8-9. Dr. Robert K. Womack, Longview, Texas, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American J. Obstetrics and Gynecology, St. Louis

38: 187-370 (Aug.) 1939. Partial Index

- Treatment of Hemolytic Streptococci Infections During Pregnancy and Puerperium with Sulfanilamide and Immunotransfusion. C. A. Chandler and C. A. Janeway, Boston.—p. 187.
- *Toxemia of Pregnancy: Types, Etiology and Treatment. M. B. Strauss, Boston.—p. 199.
- Obstetric Management of Patients with Toxemia. W. J. Dieckmann and I. Brown, Chicago.—p. 214.
- *Macrocytic Anemia of Pregnancy and Anemia of Newborn. J. A. Ritter and W. J. Crocker, Philadelphia.—p. 239.
- Treatment of Early Abortion. C. E. Galloway and T. D. Paul, Evanston, Ill.—p. 246.
- Studies on Reconstruction of Fallopian Tube: Preliminary Report of Original Technique. J. R. Geppert, New York.—p. 256.
- *Treatment of Dysmenorrhea with Testosterone Propionate: Biologic Effects of Testosterone Propionate in Sexually Mature Woman. U. J. Salmon, S. H. Geist and R. I. Walter, New York.—p. 264.
- Tubal Sterilization by Madlener Technique. E. von Graff, New York.—p. 295.
- Typhoid Fever in Pregnancy: Probable Intra-Uterine Transmission of Disease. A. W. Diddle and R. L. Stephens, Iowa City.—p. 300.
- Water Exchange and Salt Balance in Hyperemesis Gravidarum. F. L. McPhail, Great Falls, Mont.—p. 305.
- Effect of Temperature on Vitality of Spermatozoa. A. I. Weisman, New York.—p. 313.
- *Control of Pain with Local Anesthesia After Repair of Episiotomies. G. W. Hunter, Fargo, N. D.—p. 318.
- Severe Menorrhagia as Only Symptom of Essential Thrombocytopenic Purpura Cured by Splenectomy. S. L. Israel and T. H. Mendell, Philadelphia.—p. 339.
- Interstitial Pregnancy Following Salpingectomy. I. Forman, Philadelphia.—p. 344.
- Interstitial Pregnancy: Five Months' Gestation, with Observation of Phenomenon of Rupture at Time of Operation. A. J. Kobak, Chicago.—p. 346.
- Neglected Sign for Roentgenologic Diagnosis of Intra-Abdominal Dermoid Cyst. G. Danielius, Chicago.—p. 348.

Toxemia of Pregnancy.—Strauss declares that the term "toxemia of pregnancy" has served for generations and still serves as a diagnostic waste basket to cloak ignorance. Medical prepossession with mysterious and unidentified "toxins" has prevented intelligent study of the various disorders combined under this misnomer. Writers have wisely refrained from defining what toxemia is. To each the word carries certain connotations; rarely does it mean quite the same thing to any two. There remains one simple method of dividing this heterogeneous group of "toxic" women into at least two main classes, and that is by studying the state of affairs antecedent and subsequent to the "toxemia." Such study reveals that about 80 per cent of the women designated as having "toxemia" actually have chronic vascular or renal disease before and after the gravid state, and an additional 5 per cent have such disease in acute form. The remaining 15 per cent of such women have had no demonstrable abnormality before pregnancy or after the pregnancy in which abnormalities called "toxemia" occurred. Further, these women under proper management will have subsequent uneventful pregnancies. It is this group for which the designation "water-retention toxemia" seems appropriate. A low sodium intake is one means of eliminating undue water retention. The development of water-retention toxemia may be prevented by maintaining the pregnant woman's plasma proteins at a normal level by an adequate diet and avoiding excessive sodium ingestion.

Macrocytic Anemia of Pregnancy and of Newborn.—Ritter and Crocker studied the relationship between anemia of the newborn and the hematologic picture in the mother and believe that the anemia of both the mother and the infant is due to a dietary deficiency. Only one case has been encountered in the maternity service of the Philadelphia General Hospital. The response of the mother to liver therapy was inadequate and her severe reactions to transfusions precluded

their further use. The reticulocyte response was poor both during pregnancy and after parturition. Therefore, either a specific need for the liver was not indicated or an inadequate dose or an impotent extract was used. Nevertheless the mother did improve after delivery, when there was a cessation of vomiting and diarrhea and better utilization of a balanced diet. The deficiency factor which produced the anemia in the mother may possibly have been likewise deficient in the infant. It appeared that the maturation of the erythron was arrested at a fetal level because of the infant's inability to utilize a factor which it could not obtain in utero. In fact, there appears to have been little response to combined therapy and transfusions seemed only to carry the infant over until such a time as its own erythropoietic system could function at a more mature level. The infant's reticulocyte response was definitely poor in spite of marked anemia. Once a higher level of maturation of the infant's red blood cells was attained, probably conditioned by dietary intake of the deficient factor, steady improvement was noted. Oddly enough there was not an "adequate" reticulocyte response in the recovery phase. The authors can only say that the erythropoietic system was either depressed or inhibited in some inexplicable manner and improvement occurred only when this was overcome. Why such factors should work selectively on the erythropoietic system does not seem explainable except by some mechanism such as produces pernicious anemia in adults.

Treatment of Dysmenorrhea with Testosterone Propionate.—Salmon and his associates used testosterone propionate in the treatment of thirty women suffering from dysmenorrhea. The level of testosterone tolerance was established at approximately 500 mg. Administration of upward of 500 mg. resulted in the appearance, in some of the cases, of masculinization phenomena and evidence of estrogen deficiency. Normal cyclic phenomena (clinical and morphologic) returned spontaneously in all cases within two months after treatment. With doses of 300 mg. or less neither androgenic nor estrogenic deficiency effects were produced. Symptomatic relief of twenty-six of the thirty women was achieved. The suggestion is made that the biologic effects of testosterone propionate (in doses of 500 mg. or more) in women is brought about by inhibition of the gonadotropic factors of the hypophysis with consequent suppression of ovulation, estrogen and progesterone formation and menstruation, as well as by inactivation of the circulating estrogens and estrogen stores in the body. The therapeutic effects of smaller doses are probably the result of partial inactivation or modification of the action of the estrogens and progesterone. The theory is advanced that functional dysmenorrhea may be caused by an androgen deficiency.

Local Anesthesia for Pain of Episiotomies.—Reports of the successful use of soluble anesthetic solutions in rectal surgery with the purpose of relieving patients from postoperative pain have suggested to Hunter the use of this type of medication following episiotomy and other perineal repair. The results with twenty-five patients and twenty-five alternate patients taken as controls were encouraging. Two types of solutions were used: procaine base 1.5 per cent, butesin 6 per cent, benzyl alcohol 5 per cent and oil of sweet almond, the other solution being an aqueous one containing 1 per cent piperidinopropanedio diphenylurethane hydrochloride. Following repair of the episiotomy or perineal laceration, 10 cc. of warmed solution is drawn into a dry Luer Lok syringe. The solution is injected slowly into the deeper tissue, care being taken that it does not go immediately beneath the skin or mucous membranes. Following injection, massage of the parts assures an even distribution of the anesthetic. The needle is inserted about one-fourth inch on each side of the incision and the solution is injected fanwise. The injection is made while the patient is still under the effects of the general anesthetic given during repair. The water soluble solution was used for ten patients and they were free from pain until the third or fourth postpartum day, at which time the effects of the anesthesia had apparently disappeared. They then experienced as much pain as the controls. The oil soluble anesthetic, however, kept patients for the most part entirely free from distress. Healing did not appear to be impaired and no general toxic effects were observed.

Paratyphoid Fever in Massachusetts.—Feemster and Anderson state that a sudden increase in paratyphoid fever occurred in Massachusetts in 1937. From a level of about six cases a year the number reported rose to 267. The cases reported in 1937 fall readily into five groups. There were four food-borne outbreaks (220 cases), and the remainder (forty-seven) were sporadic cases; these occurred before the outbreaks and were widely scattered throughout the state. It has been impossible to trace any connection between these outbreaks. People infected in the first outbreak may have carried the organism to many other parts of the state, but so far no such individuals have been found. The fact that twenty with positive stools and eleven others with positive agglutination tests were entirely without symptoms emphasizes the importance of sub-clinical infections in this disease and illustrates why its control may be difficult. The persistence of the organism in the stools of convalescents adds an additional problem. Almost half of those who showed positive stools were still carrying the organism at the end of five weeks, one eighth at the end of nine weeks and others continued positive until the twenty-eighth, thirty-second and forty-ninth weeks and there were five permanent carriers. In the first nine months of 1938, sixty-six cases were reported. Six small outbreaks, forty-eight cases, occurred in families or in groups eating a common meal. The other eighteen cases were sporadic.

Pigmentation Following Use of Iron Salts.—Reyner reviews the reports of the eight cases of (permanent) pigmentation from the use of iron salts in the treatment of ivy poisoning. He cites an additional case of pigmentation in which complete removal of the iron deposits was effected by ultraviolet irradiation (with a water-cooled lamp). Heretofore such pigmentation has been considered permanent.

Diagnosis of Venereal Lymphogranuloma.—Decker and his associates find that the intravenous injection of 0.1 cc. of mouse brain antigen is a reliable procedure for corroborating the results of the intradermal Frei test in the diagnosis of

venereal lymphogranuloma. When they injected 0.1 cc. of mouse brain antigen into thirty-five patients with venereal lymphogranuloma of the inguinal type, thirty gave a positive and five a doubtful reaction. All twenty-one patients with venereal lymphogranuloma of the genitorrectal type gave a positive reaction. Of seventy control subjects given an injection of 0.1 cc. of mouse brain antigen, five gave a doubtful and the rest a negative reaction. A patient who had had a bubo of venereal lymphogranuloma incised four years before and had apparently had no recurrence gave a typical reaction to the intravenous injection of 0.1 cc. of Frei antigen (mouse brain) intravenously. This would support the view that the reaction to intravenous injection behaves similarly to that to intradermal injection, remaining positive after active signs of the disease are no longer present.

Thiamin Chloride for Herpes Zoster.—Since the beneficial influence of thiamin chloride in neuritis and its prevention of certain degenerative nerve changes is acknowledged, and since it has been established that the prominent feature in herpes zoster is a neuritis with degenerative changes, Goodman treated five such cases with subcutaneous administration of thiamin chloride with gratifying results. In comparing the results obtained in these cases with similar ones treated by local applications and salicylates the author finds that the former treatment is a logical and more satisfactory means of combating herpes zoster. The pain is relieved more promptly, the lesions clear up at an earlier date and the total disability time is notably decreased. In one instance a longer period (than six or seven injections of 3,000 units of thiamin chloride daily or every other day) of treatment was required. The age (71) of the patient may have been a factor. The results obtained suggest that further investigation in this field is warranted.

Vitamin K and Bile Salts for Hemorrhagic Diathesis.—Ten cases of obstructive jaundice are presented by Townsend and Mills in which the plasma prothrombin levels were low and in which there was an abnormal tendency to bleed, as indicated by prolonged clotting times. Administration of vitamin K

and bile salts restored the clotting time to normal. One failure with no adequate explanation is recorded. No abnormal bleeding followed operation on patients treated with vitamin K and bile salts. In one case there was a further disturbance in the plasma prothrombin after operation with an abnormal tendency to bleed. Prophylactic therapy is suggested as a safeguard. It is suggested that the tendency to give patients with jaundice a low fat diet predisposes to K avitaminosis, which may be accentuated further by the frequently accompanying nausea and vomiting.

Intestinal Protozoa of Man.—As information regarding the incidence of intestinal parasitic infection in Canada is lacking, Miller obtained data on the incidence of such infection in Saskatoon, Sask., by examining the stools of 254 persons. Ninety-seven of these, or 38.2 per cent, were positive for intestinal parasites. Only protozoan parasites were found. No helminth eggs were recovered from the stools, although one immature *Ascaris*, passed by a 6 year old child, was sent in by a local physician. Seven species of Protozoa were found. Five of these belonged to the class Rhizopoda and the two remaining species belonged to the class Mastigophora. Of the 254 stools examined 149 were from hospitalized and nonhospitalized clinical patients, forty of whom, or 26.8 per cent, showed parasitic infections. Only five of the infected persons harbored more than one parasite, and these were all double infections. An infection incidence of 39.7 per cent was obtained in a group of fifty-eight healthy persons. Multiple infections were found in two persons. In forty-seven orphan asylum children the incidence of parasitic infections was approximately 72 per cent. Multiple infections were quite common in this group, and of the thirty-four infected children eight had triple infections, eleven had double infections and the remaining fifteen harbored only one species. *Endamoeba coli* was found most often in all three groups. In the orphans this was followed by *Endolimax nana*, then *Endamoeba histolytica*. The observations of Fantham and Porter together with the present results, the author states, tend to demonstrate that parasitic infection is widespread throughout Canada and that even climates as severe as those found in western Canada are tolerated by this parasite. Therefore competent stool examinations should play an important part in diagnosing otherwise unexplained diseases of the large intestine.

Liver Extract for Acne Vulgaris.—Marshall used boiled liver extract in the treatment of fourteen cases of acne vulgaris and obtained satisfactory results. The subcutaneous injection of liver extract, 0.4 cc., is given so that a sufficient amount of the probably specific vitamin (probably vitamin H, termed the X factor by Boas and the skin factor by Gyorgyi) may be had. The author says this reservedly, although he is not acquainted with any other material in the extract which would increase its dermatologic potency on boiling. Since the seborrhea seemed to be the first component of the acne complex to improve, it appears that one may be dealing with a human counterpart of status seborrhoicus in experimental animals. When injectable liver extract is boiled for thirty minutes, its acne-improving factor seems to increase. When this boiled extract is given to patients already under routine liver therapy, their improvement appears more rapid.

Average Basal Respiratory Functions.—In an attempt to determine the range in values of basal respiratory functions in normal adolescents and adults and to indicate changes that take place during adolescence, Shock and Soley recorded the respiratory rate, the respiratory volume per minute, the tidal volume, the concentration of oxygen and carbon dioxide in the expired air, the oxygen consumption and the alveolar carbon dioxide tension of fifty normal boys, fifty normal girls, forty-six normal adult men and forty normal adult women. In the children the tests were begun at the ages of 11 or 12 years and were repeated at intervals of six months over a period of five years. The adults ranged in age from 27 to 43 years. The adults were chosen from staff members and from university students who were presumably healthy (although no systematic medical examination was given) and in view of their sedentary activities the average values for metabolic tests may be somewhat lower than for the general population. In the adult group as many as sixty tests were made in triplicate only on two successive days on each subject. The authors tabulate the results of these studies and in conclusion state that the following was found to prevail: 1. In boys the minute respiratory volume increases between the ages of 12 and 14 years, owing to an increase in body size. 2. In boys the respiratory rate decreases between the ages of 14 and 16, the tidal volume increases, the concentration of oxygen in the expired air decreases and the expired carbon dioxide increases. 3. In girls the respiratory volume and tidal volume increase between the ages of 12 and 14 years. 4. The composition of the expired air in girls changes between the ages of 14 and 16 as it does in the boys,

but the change is not so clearly defined. In boys there is a significant increase in alveolar carbon dioxide tension between the ages of 12 and 14 years. No significant change in alveolar carbon dioxide tension was found in girls. 5. The average oxygen consumption per minute increases from the age of 12 to 16 years in both sexes. In respect to body size there is a decrease in oxygen consumption. 6. Most respiratory functions of girls of 16 are similar to those of adult women. 7. Sixteen year old boys breathe more rapidly and have a smaller tidal volume, higher concentration of oxygen and lower concentration of carbon dioxide in the expired air and a lower total oxygen consumption than adult men.

Elimination of Methyl Alcohol.—Widmark is of the opinion that methyl alcohol is largely destroyed in the body and that the loss is at a uniform rate regardless of the amount present or the concentration in the blood. Haggard and Greenberg, to the contrary, state in summary that they find that: 1. More than 70 per cent of the methyl alcohol is eliminated in the expired air. 2. The elimination follows the principle defined for volatile substances which are largely nonreactive. 3. The amount eliminated in unit time is determined by the concentration of alcohol in the blood and the volume of pulmonary ventilation. 4. The curve obtained from the concentrations of methyl alcohol in the blood during elimination is not a straight line but an exponential curve. 5. The Widmark value β held by him to be a constant is not a constant but a variable influenced by all factors which influence the amount of methyl alcohol eliminated in unit time in the expired air.

Phrenic Crush.—Frank states that, after crushing of the main phrenic nerve for 1 cm., resection of large segments of any accessory nerves and division of the nerve to the subclavius muscle, only 50 per cent of his cases were successful as evidenced by a total paralysis of the diaphragm. Of the 50 per cent which were unsatisfactory, half showed only partial paralysis of the diaphragm; in the others an apparent paralysis was first produced and diaphragmatic movement became rees-

tablished in an average time of three months. As all the operations had been most carefully done, it became evident that other connections entering the phrenic nerve below the clavicle must exist. Therefore the author developed the following technic: The usual transverse incision for exposure of the phrenic nerve is employed. The accessory phrenic nerves are divided. The nerve to the subclavius muscle is resected as before. The phrenic nerve is then crushed for approximately 1 cm. and drawn upward into the neck for from 3.5 to 4 cm. It was thought that, by drawing the nerve upward, any filaments entering the phrenic nerve below the clavicle might be torn and hence the resulting paralysis of the diaphragm would last a much longer time. The incision is closed with subcuticular suture of fine silk with a split shot on each end of it. Since January 1935 the author has performed the foregoing operation on 246 patients and in every one complete paralysis of the diaphragm ensued. Following this type of operation the diaphragm remained paralyzed on an average of from ten to twelve months. Diaphragmatic movement then began, although that structure itself remained elevated. The amount of diaphragmatic excursion increased, and within from two to three months the diaphragm returned to its normal position and full normal respiratory movement.

Recovery from Subacute Infectious Endocarditis.—Major and Leger report their second case of subacute infectious endocarditis in which recovery occurred following sulfanilamide and sulapyridine therapy. It must be kept in mind that occasionally patients with subacute infectious endocarditis recover spontaneously. However, the authors feel that in this instance, as in the previous one, recovery was due to the therapy employed. Also in both patients the relatively short duration of the illness was probably a decisive factor.

Idiopathic Hypertension in the Young.—MacCraken wonders whether the tendency on the part of the physician to regard malignant or idiopathic hypertension as a disease of the forties may not be due to the fact that blood pressures of younger persons are taken infrequently. In other words, as one becomes older intercurrent conditions arise or symptoms develop which take one to the physician for the express purpose of "having the blood pressure taken." This hypertension is then discovered and attributed to the age of the patient, whereas an earlier examination might possibly have at least disclosed a beginning hypertension of less severity. In the

consideration of this phenomenon, as an examiner for more than 10,000 women between the ages of 20 and 30 applying for positions as teachers, the author observed among other things a distinct variation in blood pressure. While the blood pressure of most of the women ranged around 120 mm. of mercury systolic and less, about one in twenty showed a rise of from 20 to 30 mm. or more. These rises in systolic pressure were not psychic as a rule but rather persistent over a series of tests. In only about 0.1 per cent was any causative factor isolated, though in each case a careful urinalysis was made and further tests when possible. In the 500 cases only meager histories and routine examinations were obtained. Only twenty returned for reexamination following illness or some other form of leave of absence but these consistently showed the total absence of symptoms and gradual increase in tension. The absence of any "follow-up" in the majority of these cases lowers the value of the information, but the author believes that the presence of this factor in so many otherwise normal persons opens a field for conjecture and investigation.

Sulfapyridine for Pneumonia.—Since January 1939, Allison points out, 100 cases of pneumonia have been treated at the Nassau Hospital. Every patient with pneumonia admitted to the hospital was given sulfapyridine whether or not a pneumococcus was found in the sputum. If a patient was desperately sick on admission or did not respond promptly to the drug, serum also was given. The sputum was examined at least once in ninety-seven cases. A pneumococcus was found in seventy, and twenty-seven were negative for pneumococci. The types of pneumococci found were I, III to VIII, XI, XIV to XXIII, XXVIII and XXIX. Blood counts and urinalyses were done in all cases. The severity of illness of

these 100 patients was comparable to any similar series of patients with pneumonia admitted to the hospital during recent years. Sixty-one patients were admitted before the fourth day of the disease, twenty on the fourth day and nineteen after the fourth day. Forty-two cases occurred in children less than 10 years of age, nine of these occurring during the first year. The average number of days spent in the hospital was 13.8. Four of the 100 patients died, one infant and three adults. Six of the seventy blood cultures performed were positive; three were type I, two type VIII and one was unidentified. One of the patients with type I pneumococci, with a very heavy growth, was addicted to alcohol, had hypertension and made a dramatic recovery. One, with a heavy growth, died in twenty-four hours in spite of 400,000 units of serum and sulfapyridine. The third patient recovered after 300,000 units of serum and 46 Gm. of the drug. Both patients with type III pneumococcus recovered. The unidentified case also resulted in recovery. An initial dose of 2 Gm. of the drug followed by 1 Gm. every four hours was given in most of the adult cases. Of the fifty-eight adults, twenty-eight received a total of less than 15 Gm., fifteen received from 15 to 25 Gm., ten from 25 to 40 Gm. and five more than 40 Gm. The average total dosage was 19 Gm. The author's impression is that small doses, certainly much smaller than the 25 Gm. originally suggested, will prove sufficient in many cases. In children a daily dose of 0.2 Gm. per kilogram of body weight, reduced to 0.1 Gm. after the first twenty-four hours, is suggested. Children seem to tolerate the drug so well that in some cases much larger amounts were given. The average total dosage for children was 7 Gm. This total dosage was well tolerated by each of the nine infants. As a rule, the temperature in an interval of from twelve to thirty-six hours showed a marked drop and with it the pulse and respiratory rate. The general appearance and sense of well being of the patient showed a corresponding improvement. The temperature response seems to be a good index of the extent of improvement. Twenty-two of the twenty-seven patients in whose sputums no pneumococcus was found showed a prompt response to treatment. It is possible that further sputum examinations would have revealed pneumococci; otherwise such a high percentage of prompt responses in nonpneumococcal pneumonias would not be expected. There were no serious toxic signs in any of the cases. The mortality rate at the Nassau Hospital for all pneumonias during the last four years was 19 per cent in 1935, 20.9 in 1936, 18.1 in 1937 and 11 per cent in 1938.

Hodgkin's Disease with Herpes Zoster and Varicella.

—Marcellus reports a case with the simultaneous coincidence of Hodgkin's disease, herpes zoster and varicella. The vesicular eruption of varicella had a localizing effect on the herpes zoster. Unlike some of the others formerly reported, this patient showed the clinical characteristics of varicella with symmetrical lesions which had thin and easily ruptured vesicles, containing clear fluid at first which later became pustular; the eruption spread rapidly and formed typical crusts; the mucous membranes were involved and from the history there might have been exposure to varicella, during leave from the hospital the first day of which was just fourteen days prior to the vesicular eruption, and the characteristic fever immediately preceding an almost typical eruption strongly suggested varicella or variola, but it is believed that, as he had been successfully vaccinated, the latter may be ruled out. This case undoubtedly represents the simultaneous existence of slowly progressive Hodgkin's disease, proved beyond a doubt by several biopsies at different laboratories all of which agreed, and

herpes zoster closely followed by varicella, with no recurrences of either cutaneous eruption after the patient was discharged from the hospital following the recovery from the cutaneous lesions.

Cystic Disease of Lung.—Sante refers to abnormal confined collections of fluid within the lung as cysts and to air-filled cavities as pneumatocoles. One of the most common types of lesion referred to as cystic disease is seen as multiple thin-walled pneumatocoles, clustering about the larger bronchial branches in the hilar regions and adjacent areas, giving rise to the condition referred to as cystic bronchiectasis. When the cavities are small and their walls are thick the term honeycomb has been applied to their appearance. Fluid cysts and pneumatocoles of the lung arise as results of definite derangement in the lung structure. These derangements can be either congenital from faulty embryologic development or acquired from infection and fibrosis. The factors which primarily influence the degree of inflation of such pneumatocoles, in which free bronchial connection is present, are the relationship of the resistance of their walls to the resistance of normal alveolar structure supplied by a bronchiole of equal size to the opening supplying the cavity. The pressure in the pneumatocole cannot exceed atmospheric pressure. On x-ray examination there should be no deviation of the mediastinum at any time. In instances in which a simple check-valve opening permits entrance of air on inspiration but checks it on expiration, the pneumatocole will enlarge in size until an equilibrium is established; the pressure within the pneumatocole cannot become greater than that of the atmosphere at maximal inspiration but may exceed this at expiration, also causing the mediastinum to be in normal position on maximal inspiration but displaced to the opposite side on expiration. Pneumatocoles which continue to expand showing higher than atmospheric pressure at all times during the respiratory cycle would seem to require

the addition of some unusual pumping force to account for their expansile character. Fluid cysts may result only when the defect involves a bronchial structure which still retains secretory power. Pneumatocoles arising from the alveolar structure as a result of emphysematous involvement should not be preceded by fluid cysts, since they are not lined by secretory epithelium.

Reducing Toxic Period in Hyperthyroidism.—For some years Barrow has believed that the dosage of x-rays given in the treatment of hyperthyroidism, even by those of wide experience, is insufficient for the best interests of the patient. As the mysteries and intricacies of the ductless gland system unfold, it is well to bear in mind the possibility that there may be other functions of the thyroid than those now recognized. Surgical removal of the thyroid or proper irradiation of the gland alone will restore the patient to normal. However, no organ of the body should be removed because of dysfunction or excess function when it is possible to correct its functioning processes. The depressant action of x-rays in all conditions characterized by hyperfunction or excess cell activity is recognized. The only argument which has been advanced against roentgen therapy for hyperthyroidism is the time usually consumed in bringing the patient to a nontoxic state. Small dosage at long intervals seems to be the practice generally followed. The object of the surgeon has been to remove with one stroke the source of toxicity, the thyroid gland. Why not, then, suppress this toxicity as abruptly by radiation? Following the use of comparatively large doses of x-rays in extremely toxic cases of hyperthyroidism, the author has never seen any ill effects. On the contrary, by the application of rather intensive dosage only good results have been seen, the most toxic cases becoming nontoxic in from four to ten weeks rather than in from six to nine months (the usual time required with small doses of x-rays). If the metabolic rate is high, plus 50 or more, the application of 750 roentgens weekly, the dose divided over three areas, right and left anterior lateral and posterior with a kilovoltage of about 130 and 3 mm. of aluminum filter is the minimal dosage indicated. This may be repeated from six to eight times at intervals of seven days, with no ill effect on the skin. The metabolic rate should be checked each week and the doses should be spaced at longer intervals or decreased as the metabolic rate falls. The metabolic rate should be reduced to zero before treatment is discontinued; otherwise an exacerbation will inevitably follow. The fear of myxedema following irradiation is hardly to be considered when radiation is applied intelligently. Intense radiation given over the thyroid area in cases in which the thyroid is normal has not shown any bad effects on the gland. Under circumstances in which it is difficult because of distance or other causes to give weekly applications, still more intensive dosage may be applied at intervals of fourteen days (200 kilovolts, 0.75 mm. of copper filtration, with 1,200 roentgens distributed over three areas). This technic may likewise be repeated with safety but will require as many applications, because the metabolic rate falls rapidly. In the treatment of all cases, foci of infection should be removed, iodine withheld and quinine used liberally, with of course, restrained activity as indicated. Two charts are presented indicating the conditions existing in two typical cases of hyperthyroidism, with the treatment given and the result obtained.

Electro-Encephalogram as Aid in Clinical Neurology.

—From experience to date in the examination of intracranial tumors, although the electro-encephalogram is surprisingly accurate in localization in most cases, Krynauw states that the additional help given by ventriculography should not be dispensed with when operation is contemplated. Information as to the depth of a neoplasm, its absolute size and its relation to the ventricles, basal ganglions and the like can be obtained at present only by adequate air studies; and such information is essential in planning the scope of an operation or deciding on the operability of a tumor. Electro-encephalography by itself is no short cut toward the establishment of the anatomic and pathologic diagnosis of intracranial lesions. Considerable interest is attached to the study of the epilepsies by this method. Nevertheless it is in the epileptic group that the greatest difficulty occurs in the evaluation of results. In many cases of the group known as "idiopathic grand mal" there is constant electrical flux, sometimes generalized and arising from the whole cortex but often arising from one or more foci. In some cases the changes resemble closely those found in association with expanding lesions. In some cases, too, there is a tendency toward a frequent shift of the focus. These remarks apply only to those cases of epilepsy in which there is a "resting focus" of electrical flux; that is, changes which can be detected between the actual fits. These changes are constant in that individual and do not bear any time relation to the actual fits. There is, however, evidence that before a fit, perhaps for hours, a day or even longer, there is an accession in the electrical changes. On records taken at such times, bursts of waves of increased amplitude and varying rate appear not at all unlike the "larval" attacks of petit mal described by Lennox and his associates. There are many cases that clinically appear to be idiopathic grand mal in which the author has not been able to detect any abnormality of the electrical rhythm. Why this should be so is difficult to decide, but from his experience there seems to be some relation between the resting focus and cortical degeneration. In cases in which numerous minor seizures occur there is an almost constant electrical flux with occasional sudden bursts of increased activity which have been described as larval or subclinical seizures, and then again the actual petit mal attacks with even greater alterations of amplitude. The pyknolepsies are said to fall into this group. It has been claimed that in the so-called traumatic epilepsies there is never any evidence of a resting focus of electrical abnormality. The author's experience supports this, for many cases with fits after a head injury have yielded negative observations on electro-encephalography. However, he has records of several cases of gross localized cortical damage in which alterations of potential were observed, similar to those found with expanding intracranial lesions. In such cases he has assumed an underlying area of gliosis. In patients in whom the onset of fits occurs in later life after the age of 40, the possibility of an expanding lesion should be ruled out, and air studies are often called for.

In the author's series the electro-encephalogram has always been normal when the encephalogram was normal, but further work is necessary before the reliability of the method can be assessed accurately.

Ureteral Catheterization in Pyelitis of Pregnancy.—

During a period of four years Dix and Evans state that eighty-four cases of pyelitis of pregnancy were admitted to the London Hospital, and of these only seven required ureteral drainage: five because of failure to respond to alkali therapy and two because of excessive vomiting, making the administration of alkali impossible. Nine ureteral catheterizations were carried out. In one instance the second catheterization was necessary because the first catheter was removed by a nurse when the patient returned to the ward, and in another the second catheterization was performed three and a half months after the first during a recurrence of pyelitis. In no case was it necessary to use an anesthetic. Catheterization of the ureter during pregnancy is not easy and should be carried out only by the expert. If it should ever be necessary for the relatively inexpert to attempt catheterization in the later stages of pregnancy, an anesthetic should be given to minimize the difficulties. When the ureteral orifice has been identified and the catheterization has begun there should be no difficulty, and the fact that the catheter has reached the renal pelvis will be at once evident from the rapid flow of urine, which is considerably in excess of that from a ureteral catheter of the same size passed into a normal pelvis. In cases in which there has been a complete block at the pelviureteral junction the flow may be rapid. It is advisable to pass as large a catheter as possible. The sizes used have been 10 and 12. Great care must be taken, in withdrawing the cystoscope, to avoid displacement of the catheter. The catheter is attached to the leg and the urine is allowed to drain into a bottle. The catheter was usually left in place for three or four days. However, equally good results might be obtained if the catheter remained in place for only one or two days, although there would perhaps be a slightly increased risk of recurrence. It should be removed at once if urine ceases to run freely and gentle syringing fails to reestablish the flow. The effect of catheterization and drainage alone on the seven patients was so good that no additional treatment was needed except the continued administration of citrate. Premature induction of labor should rarely, if ever, be necessary, even in severe pyelitis of pregnancy. One case of postpregnancy pyelitis was also treated successfully by catheterization.

Amicrobic Pyuria.—Weytlandt directs attention to cases of cystitis and pyelocystitis in which the urine is free from microorganisms. He thinks that in cases of this type it is necessary to consider first the possibility of renal tuberculosis even in the absence of acid-resistant bacilli. Another factor that must be considered is that during infections with colon bacilli there are periods in which no organisms are found in the urine even if cultures are made. The cases mentioned so far are false cases of amicrobic pyuria, but there are also cases of true amicrobic pyuria. In this connection the author mentions first cases of leukocyturia that are caused by mechanical or chemical irritation. Then there is a group of pyurias in which all cultures, including those for tubercle bacilli, remain sterile and in which even inoculations into guinea pigs produce negative results. The author says that it was Söderlund who in 1922 first called attention to this type of pyuria, which can be considered as a separate disease entity. The number of cases which have been reported since then is small, but this amicrobic pyuria is nevertheless of practical importance. Those who know it will doubtless have occasion to diagnose it. Moreover, this disorder, which formerly was extremely chronic and annoying is now curable, Wildbolz having discovered that it yields promptly to treatment with neoarsphenamine. In view of the fact that this form of amicrobic pyuria was first described by Söderlund and was first successfully treated by Wildbolz, the author suggests that it be designated Söderlund-Wildbolz disease. The etiology of the abacterial pyuria is still unknown, but in view of the curative effect of neoarsphenamine it is suggested that an infectious process is involved but that the causal agent is not necessarily a spirochete. The author describes the history of the case of amicrobic pyuria which he himself observed. The disorder began with hematuria, which was followed by cystitis. The urine contained large numbers of leukocytes but no microorganisms. Syphilis could be ruled out on the basis of the negative outcome of several serologic tests. When treatment with methenamine, phenyl salicylate and sulfanilamide had failed, the author resorted to intravenous injection of 150 mg. of neoarsphenamine. The first dose having produced considerable improvement, the patient was given two additional injections of 300 and 450 mg., respectively, at intervals of five and six days. The author thinks that two injections will suffice in most cases.

Presse Médicale, Paris

47: 1221-1228 (Aug. 9) 1939

- *Condition of Adnexa in Uterine Fibromyomas and Their Surgical Consequences. A. Chalié.—p. 1221.

Adnexa in Uterine Fibromyomas.—Chalié cites prognostic and physiologic considerations which indicate that operative treatment is advisable for the majority of patients with uterine fibromatosis, but he also stresses that the idea of conservation should be foremost in the mind of the surgeon, since the majority of women who require treatment for uterine fibromatosis are of the age group between 28 and 50; that is, they are women who are in the period of genital activity, and the majority still menstruate. As regards the problem of conservation, attention must be given particularly to the uterine adnexa, and the first question which presents itself is the anatomic condition of the adnexa in patients with uterine fibromyoma—in how many cases of uterine fibromatosis the adnexa are diseased. In order to throw light on this problem, the author carefully inspected the adnexa of 212 patients who received surgical treatment for uterine fibromas. He found the adnexa diseased in 161 of the 212 cases, more than three fourths. Most frequent were the purely ovarian lesions, which were observed in 104 of the 212 patients. Purely tubal lesions were comparatively rare, existing in eleven of the women. Mixed tubo-ovarian lesions were detected in forty-five cases. The author discusses to what extent it was possible to employ conserving methods in the surgical

treatment of these 212 patients. As regards the uterus, conserving operations could be employed in only twenty-four of the cases. These include six supra-isthmic hysterectomies, three hysterectomies of the fundus and fifteen myomectomies. In the other 188 cases the uterus had to be mutilated: total hysterectomy in thirty-eight and supravaginal hysterectomy in the other 150. Conservation of one or both of the adnexa was possible in ninety-eight, nearly 50 per cent of the cases. From this the author draws the conclusion that in spite of the frequency and severity of the adnexal lesions associated with uterine fibroma it is possible to preserve all or part of the ovarian apparatus in nearly 50 per cent of the cases.

Basophil Adenoma of Hypophysis.—Austregesilo and his associates studied the clinical, endocrine and roentgenologic aspects of a case of Cushing's disease in which the diagnosis could be confirmed by anatomopathologic examination. They give a detailed description of the history of the patient, a woman aged 44. Since 1914, when she had entered a psychiatric hospital for the first time, she had become extremely obese and hairy. In 1937 she presented severe obesity, hirsutism, virilization and anomalies of the menstrual cycle. Her face was round and moon shaped. Her organic resistance was reduced and she was easily fatigued. Her mentality was oligophrenic. Roentgenography of the sella turcica showed normal outlines. After describing the results of the humoral examinations, the authors show that these, like the clinical syndrome, indicate basophil hypophysial hyperhormonism with involvement of the other endocrine glands. The necropsy disclosed in the lateral portion of the prehypophysis an adenomatous formation, the size of a small pea, which at some points was separated from the glandular parenchyma by a thin capsule, whereas at other points there was no separation. The cells of the adenoma showed basophil granulation. The authors point out that the patient does not present the complete symptomatology of Cushing's disease, but they also show the multiple variations to which the clinical aspects are subject as a result of the pluriendocrine-metabolic deviation, according to whether there is a stimulating or an inhibiting preponderance of certain groups of cells of hypophysial secretion. They also direct attention to the relations between the hypophysis and the diencephalon. They think that the incomplete clinical forms of Cushing's disease are the most frequent, but because of the difference in symptomatology the clinical diagnosis of these forms presents difficulties.

*Panic: Nature, Causes and Treatment. E. Bircher.—p. 768.
Alcoholism in Medical Clinic of Geneva During the Years from 1933 to 1936. M. Roch.—p. 772.

Panic: Nature, Causes and Treatment.—Bircher points out that during catastrophes treatment of the psychic injuries is as important and as much the duty of the physicians as is that of the physical injuries, and so he directs attention to the problem of panics which occur not only during wars but also in the course of earthquakes, mine accidents, fires in theaters, shipwrecks, explosions, devastations caused by meteorologic catastrophes, volcanic eruptions, famines, epidemic diseases and so on. Panic is a fear neurosis which develops in a small or large number of persons under the influence of great fear brought on by a catastrophe. This emotion may result in a sudden impairment of the consciousness and distraction, which leads to senseless excitement or, more rarely, to stuporous inhibition. The thin upper layer of consciousness is destroyed by the unexpected catastrophe and the strong instincts of the subconsciousness come suddenly to the surface and become dominant. The most important of these instincts is that of self

preservation. If this instinct becomes manifest in a mass, the phenomenon of mass fear results, which may degenerate into wild, uncontrolled flight. At the onset not all the members of the group are necessarily in the grip of this fear. It is enough that some, usually those having a psychopathic constitution, the unstable, succumb to the threat and in a mysterious, epidemic suggestion, everybody, even the strongest, is carried along. The author further discusses various types of panic, military, economic and so on, and points out that panics are observed also among animals. He thinks that the attitude toward life plays a part in the development of panics; that Asiatics and Mohammedans, whose attitude is more fatalistic, are less likely to be influenced by catastrophes than are Europeans, for instance. Some peoples seem to be more predisposed to panics than are others, but none are entirely immune to them. The degree of reactivity may differ, but culture or civilization does not have much effect in this respect, for panic is an atavism toward the primitive, perhaps even to the animal. The greater the discipline among a people, the lesser is the danger of panic. Declining and weakened peoples are more subject to panic than are others. In the therapy of panics, personalities with self possession, resolute determination and clear vision are most important, for they alone will know how to overcome the panic by the power of suggestion. Psychologic education of the masses and strengthening of the authority are important in counteracting the tendency toward panics. Discipline which comes from within and which is based on conviction or a great idea is stronger than that which is imposed from the outside.

Heredity in Pernicious Anemia.—Citing reports from the literature, Kaufmann and Thiesen show that it cannot be doubted that hereditary factors play a part in the pathogenesis of pernicious anemia. In order to obtain more information about this problem, they made studies on the relatives of patients with pernicious anemia. Their material comprises forty-eight family groups, in which 168 persons were examined. Specimens of gastric juice of an additional twenty-three relatives were examined, and anamnestic data of a number of other relatives were obtained by means of questionnaires. Summarizing the results obtained in these studies, the authors say that they detected the multiple occurrence of pernicious anemia in eight of the forty-eight families, that is in 16.7 per cent. Once it occurred in uniovular twins, once in three sisters, twice in mother and son, twice in brothers, once in brother and sister and once in cousins. That they detected multiple familial occurrence of pernicious anemia more frequently than did other investigators is ascribed by the authors to the fact that most of their patients with pernicious anemia were of an advanced age so that an existing predisposition in siblings and other relatives had time to become manifest. The multiple familial occurrence of pernicious anemia is so considerable that accident cannot explain it and heredity must be assumed. The authors also observed the concurrence in the same families of pernicious anemia and essential hypochromic anemia. They say that the familial concurrence of these two forms of anemia has been reported so frequently that a common hereditary factor must be assumed. A pathogenic connection of the two disorders is indicated also by the repeated observation of a transition of essential hypochromic anemia into pernicious anemia. The multiple appearance in their material of anacidity, of subacidity, of hematic symptoms resembling those of pernicious anemia, of soreness of the tongue and of atrophy of the lingual mucosa is regarded by the authors as further evidence of the transmission

of hereditary factors of pernicious anemia. They gained the impression that the increased incidence of anacidity or subacidity in the families of patients with pernicious anemia is of especial significance because its hereditary transmission apparently is dominant. Their statement that the results of their investigation indicate hereditary origin in about half of their cases does not signify that in the other cases signs of hereditary transmission were entirely absent; cases in which there were an increased color index and hypersegmentation but normal gastric secretion were not grouped with those in which hereditary origin was certain. They consider it possible that heredity plays a part in all cases of pernicious anemia. On the other hand, they think that there may be purely exogenic, nonhereditary cases of pernicious anemia.

Subcutaneous Carbon Dioxide in Angiospastic Disorders.—Mom points out that carbon dioxide stimulates the respiration as proved by the administration of oxygen-carbon dioxide mixture in cases of asphyxia. He discusses particularly the stimulating effect of the subcutaneously administered gas on the terminations of the vagosympathetic nervous system in the skin. Having observed that Romeuf employed this treatment with success in vasomotor disturbances, such as intermittent claudication, acrodynia, acrocyanosis and Bürger's disease, the author also decided to try it. He injects each time from 40 to 50 cc. of the gas under the skin of the arm or leg. If necessary, from 300 to 400 cc. can be injected in one session at different sites. The use of a manometer is desirable so that the pressure of 2 meters of water (about 150 mm. of mercury) is not exceeded. A patient who is resting requires from four to sixteen hours for resorption, an ambulatory patient several hours. The vasodilator effect of this treatment produces a better blood perfusion of the treated area.

Effective Insulin Suppository.—Brahn and Langner say that rectal administration of insulin has not been possible heretofore because insulin is destroyed by tryptic ferments. The authors decided to find a way to protect the rectally administered insulin against destruction (1) by adding acid in order to protect it against tryptic digestion and (2) by adding substances that increase surface tension so as to increase the rapidity of absorption. In numerous experiments on animals and human subjects the authors demonstrated that suppositories consisting only of insulin and cocoa butter (theobroma oil) are ineffective in animals as well as in human subjects. However, by adding acid it was possible to make the insulin effective and protect it against tryptic influences. The authors experimented with hydrochloric acid and with several organic acids such as lactic acid, acetic acid, citric acid, tartaric acid and palmitic acid. They found most effective a mixture of lactic and palmitic acids. Because the latter acid has a melting point of 60 C., it must be mixed with cocoa butter in a ratio of 15:85, thus bringing the melting point to about 33 C. Further experiments proved that the addition of saponin increases the efficacy of insulin suppositories. Experimenting with various types of saponin, the authors found that saponaria saponin, although harmless in oral administration, is dangerous in rectal administration. Other saponins were found to be harmless, however. Following rectal application of the insulin suppositories prepared by the authors,

the effect on the blood sugar is rapid, the maximum being reached in from thirty to forty minutes. After that the action decreases rapidly. Increasing the insulin dosage not only intensifies the action but also prolongs its duration.

Angina Pectoris and Pressoreceptor Regulation. S. Wassermann and H. Weber.—p. 589.

Hypophysial Deficiency in Alopecia.—Kylin and Dicker report the clinical analysis of alopecia in twenty-nine persons (thirteen male and sixteen female) ranging in age between 5 and 61 years. A hereditary tendency was established for nine of the fifteen patients questioned with regard to familial occurrence. Two cases are given in detail and their mendelian significance pointed out. The disease, characterized by partial or total loss of hair at all areas of the body, did not affect the general health, left basal metabolism and blood pressure nearly always normal, occurred in six cases synchronously with the first menstruation, was accompanied by dental caries in fourteen, by brittleness of the nails and cutaneous modifications in fifteen, by constipation in half of the cases and by the appearance of anxiety, frequent headaches and constant chilliness and asthenia in 50 per cent at its first manifestation. With endocrine abnormality clearly in evidence, the authors were led to eliminate the direct pathogenesis of the sexual, adrenal, thyroid and parathyroid glands and to concentrate on the hypophysis as the causative factor. In this they were supported by the clinical evidence of a previous case incorporated in the paper. Therapy of the cases studied was twofold: (1) oral doses of hypophysial (anterior lobe) extract, which resulted in three complete cures, two partial cures and one negative issue; (2) grafting of two whole calf hypophyses, yielding two complete, four partial and two negative issues. (The previous patient was therapeutically managed both ways and cured after intervention of pregnancy and recidivation of alopecia.) The authors buttress the paucity of their cases and cures by reference to those of other therapists. They regard the amelioration or success obtained with other endocrine medicaments as confirmatory of their own, in view of the dominance of the hypophysis in the endocrine system. Among the conclusions of the authors the following may be mentioned: 1. Complete alopecia affects both sexes at all age levels, with the greatest incidence at the age of 23 to 25 years. 2. Total alopecia is heritable and obeys the mendelian laws. 3. The hypophysis plays an important part, though it cannot at present be determined whether the whole gland is involved or, only one of its parts and whether the gland affects pilositis directly or through other endocrine glands. 4. Grafting with whole calf hypophyses gives just as good results as oral or parenteral administration of hypophysial extract.

- *After-Examination of Patients with Uncomplicated Concussion of Brain, with Special Regard to Importance of Duration of Primary Rest in Bed. S. With.—p. 2057.
Icelandic Mud for Mud Packs. K. Hannesson.—p. 2072.

After-Examination in Concussion of Brain.—With asserts that brief individualized confinement to bed in uncomplicated concussion of the brain does not seem to give less favorable results either as to the time when the patients are able to resume their full work or as to the number of patients whose injuries are permanent than in corresponding groups treated with prolonged rest in bed, nor is the tendency to graver permanent injuries greater. He reviews the 394 cases (272 of mild, ninety-seven of moderate, twenty-five of grave concussion) treated in Sundby Hospital from 1924 to 1934 with individualized confinement to bed according to the duration of the symptoms. In 257 cases (65 per cent) the rest in bed was for less than

one week, in ninety-five (24 per cent) from one to two weeks, in thirty-one (8 per cent) from two to three weeks, in eight (2 per cent) from three to four weeks, in three (1 per cent) four weeks or more. He examined 328 patients (84 per cent) in their homes; 9.6 per cent could not be traced and 6.4 per cent had died, presumably not from accident. Permanent sequelae were found in 16.1 per cent (severe sequelae in six cases, moderate in eight, slight in seven, very slight in twenty-seven). The tendency to permanent injury, he says, increases with age. There was no demonstrable connection between the severity of the acute symptoms and the occurrence of permanent sequelae. Work was resumed within one month after discharge by 66 per cent of the patients and within from one to three months by 18 per cent. Less than 1 per cent were permanently disabled. Of 250 without permanent injury, 57 per cent were wholly free from symptoms one month after discharge, 73 per cent in all three months after discharge. In the remaining 27 per cent the general postcommotional symptoms disappeared more slowly.

Experiences with Three Carcinoma Reactions. L. Furuhjelm.—p. 2082.
*Sedimentation Reaction in Ischialgias. H. Hortling.—p. 2086.

Sedimentation Reaction in Ischialgia.—Hortling made sedimentation tests three or four times, at intervals of one week, in 198 cases of grave ischialgia. An increased sedimentation reaction was established in fifty-two cases (26.3 per cent). In eighteen the increase was transient; in eleven of these the ischialgic symptoms had originated in connection with an infectious disorder; seven were considered cases of "genuine" ischialgia. In thirty-four cases there was a constantly increased sedimentation reaction, in sixteen explainable by simultaneous general disorder, in eighteen without demonstrable cause. In the cases connected with infections, unlike those in the other groups, there was no history of earlier ischialgic symptoms. Neuritic symptoms were present equally often in the cases with normal and those with increased sedimentation, and the sedimentation was not increased more often in the bilateral than in the unilateral cases. No connection was demonstrable between rise in temperature and increased sedimentation. Since from his results the author assumes that one fourth of the cases of ischialgia are, at least in part, combined with disorder of local or general nature which causes increased sedimentation, he considers the sedimentation reaction important because of the therapeutic possibilities.

What Was Cause of Death? Epidural Hematoma or Hemorrhage in Brain Stem? O. Berner.—p. 2104.

Vertebral Fracture in Metrazol Shock.—Dedichen says that while fractures, usually of the neck of the femur, but also of the scapula and the pelvis, have been described in connection with metrazol shock, he has found but one instance reported of compression fracture in the vertebral column due to this treatment. In a short time he has observed such fractures, some grave, in six of eighty cases treated in his hospital, and similar fractures have been noted in other hospitals since attention has been called to them. These fractures do not occur in epileptic patients because the tonic stage is not so long and violent as in the metrazol attacks; the injury occurs during the tonic stage. The fractures resemble those seen in tetanus. The anterior part of the vertebra is almost always compressed, without injury to the spinal cord, and the posterior part remains intact. There is a slight gibbus. The fracture usually occurs between the third and the ninth thoracic vertebra, where kyphosis is most marked. The author now avoids these fractures by placing a firmly folded blanket under the region of the scapula, removing the pillow and having the patient stretched full length during the metrazol seizures, not allowing him to double himself up during the attacks. The most exposed anterior parts of the vertebra are thus kept apart and the stronger posterior parts receive most of the pressure.

THE MANAGEMENT OF EXOPHTHALMIC GOITER IN A GENERAL HOSPITAL

RICHARD LEWISOHN, M.D.

B. S. OPPENHEIMER, M.D.

AND,

SOLOMON SILVER, M.D.

NEW YORK

It is a well known fact that the surgical treatment of exophthalmic goiter in centers highly specialized in thyroid surgery may be carried out with a practically negligible mortality. In spite of many serious complications of this disease (hypertension, arteriosclerosis, diabetes and auricular fibrillation) the mortality is much lower than in chronic appendicitis or inguinal hernia when the latter diseases are associated with cardiac or other complications. This low mortality, however, is usually not maintained in general hospitals, where mortality figures are often from five to ten times higher than in special thyroid clinics. These clinics with a few thousand goiter operations a year have naturally developed an almost perfect organization both medically and surgically. It has been claimed that a similar organization cannot be maintained in a general hospital. Undoubtedly this statement is correct unless an organization within a general hospital is created for the proper management of this group of cases. That an efficient organization for the handling of thyroid cases can be created in any general hospital without great difficulty is proved by this report.

Most general hospitals have a number of surgical and a number of medical services. If the cases of thyroid disease are distributed or rotated among these different services, it is impossible to establish the organization necessary for the proper management of these cases. In other words, grouping the cases is the first step in an attempt to reduce the mortality and improve the results. Naturally, grouping requires continuous services. Rotating the services (two or three groups of men being in charge of the service during a calendar year) is incompatible with the development of a high standard of efficiency.

The present organization at this hospital was established in 1931. It was decided to concentrate the diseases of the thyroid gland in one medical (Oppenheimer) and one surgical (Lewisohn) service. Patients sent in by members of the other medical service (Baehr) were admitted to the Baehr service and were operated on by the same surgical unit. They are included in this survey. However, patients sent to the wards of the hospital by members of the other three surgical

groups were operated on in their respective services. They comprise a very small number and are not included in this statistical review.

ORGANIZATION AND MANAGEMENT

The patients were usually admitted to the medical wards of only one medical service, where they were seen by the medical members of the group. Whenever possible the patients were placed in a small back room containing only two or four beds and were not placed in the large general ward. They were encouraged to believe that a special interest was being taken in them by the group, and frequent opportunities were offered them for a detailed discussion of their real or fancied complaints. Any one who has handled these patients knows how important it is to be a "good listener." Since many of the patients were very apprehensive, as little as possible was done in the way of study until they had become accustomed to the hospital atmosphere. Psychotherapy of the most simple and practical sort was carried out, and the patients came to feel that they had a friend in the medical adviser. If patients were obviously in fear of surgery we usually answered their early questions regarding the necessity of surgical treatment by saying that the type of treatment would depend on the results of the "tests." As confidence developed, most of the patients were told of the advantage of surgery and they readily signed consent for operation. In some cases it was considered unwise to deal directly with the patient, and consent for the operation was obtained from a responsible relative and the operation done without the patient's knowledge, avertin with amylene hydrate being used as a basic anesthetic after the patient had been prepared by daily enemas of an inert substance for some time before the scheduled operation.

The patients were put to bed and kept there for at least several days. After that, lavatory privileges were allowed the less sick. All were given unlimited diets and encouraged to take extra nourishment between meals. No special effort was made to restrict protein or favor fat in the diet, and supplementary vitamins were rarely given. Relaxation packs were used only infrequently, but they sometimes seemed to help excited patients. The usual sedative was phenobarbital in doses of from 0.03 to 0.06 Gm. three times a day. If cutaneous rashes developed we usually substituted chloral hydrate and bromide for the barbiturate.

The occasional patient who remained very agitated, and particularly if diarrhea developed, was often helped by opiates, usually in the form of powdered opium in doses of 0.06 Gm. three or four times a day. We have no fear of opium medication in these patients for short periods, and it seems to exert a particularly beneficial effect in some instances.

A determination of the basal metabolic rate was done on admission and again one or two days later. If the rate was not excessively high, plus 50 per cent or less, the patients were usually given compound solution of iodine directly after preliminary studies had been made. It has been the rule of the group that the administration of iodine is really the first stage of the operation, and it is never begun until the patient has been seen by the surgeon and his consent for the administration of iodine obtained.

The more severely ill patients—with a basal metabolic rate over 50 per cent—and those who gave evidences of extremely acute disease, even if their basal metabolic rate was relatively low, were given a period of complete bed rest and sedation for such a period as was thought necessary to secure the maximum advantage of these aids before resorting to iodine. We think that the effect of the iodine is greatly enhanced if full advantage is taken of the tendency of the disease process to moderate under bed rest and sedation. Iodine was administered in the form of U. S. P. compound solution of iodine, and

patients who presented the picture of severe illness, and yet the basal rate was only moderately elevated. On the other hand, we have seen patients whose basal metabolic rate was plus 70 per cent or even plus 80 per cent and who did not impress us as being very ill. We have always regarded seriously those patients who fail to gain weight or whose basal metabolic rate remains high under rest and compound solution of iodine or in whom extremely agitated states, psychotic features, vomiting or diarrhea develops.

If an infection of the upper respiratory tract develops during the course of iodine medication, the operation is delayed until at least three days after all signs of the infection have cleared. The iodine is of course continued.

In the more severe cases one of the medical men usually arranged to be present at the operation to be able to consult with the surgeon as to the extent of the operation, and particularly whether the operation should be done in one or two stages. In most cases this decision was reached before the patient left the medical service. With regard to operation in two stages, our attitude has been that it affords a definite reduction in mortality and morbidity, and all patients about whom a serious doubt is entertained should be operated on in two stages. If there is a question as to the ability of the patient to stand a single stage operation, it is always better, we believe, to subject the patient to the inconvenience of two operations rather than to commit an irremediable error by subjecting the patient to more surgery than he can stand in a single stage. We have never seen any serious difficulty in the second stage, even in patients who were very acutely ill and who had had a stormy first stage.

In practically every case avertin with amylene hydrate was given by rectum as a basic anesthetic before the patient was taken to the operating room. We have had a large experience with avertin with amylene hydrate and recommend it highly for thyroid surgery. It spares the patient the tension and emotional excitement caused by the transfer to the operating room. In order to counteract any possible apprehension, the patient is given a hypodermic injection of a sterile salt solution and an inert enema on the two days preceding operation. Thus the patient reaches the operating room without the slightest emotional upset. The optimal day for the operation varies with the individual patient.

When the patient arrives in the operating room the pulse is counted. In a few cases when the pulse was over 150 beats a minute while the patient was under this anesthesia we have postponed the operation and have sent the patient back to the ward. We have never regretted this conservative attitude. However, decision as to the postponement should not be arrived at without bearing in mind that in many instances an accelerated pulse rate during basic anesthesia will drop 40 beats a minute when the patient is under complete anesthesia. The general anesthetic consisted of gas and oxygen and some ether. In a few instances in which there was a very severe heart lesion we have used ethylene gas or local anesthesia only.

An ever recurring acute problem in the management of this disease is what to do with the patient who has received iodine for a considerable period of time and yet fails to improve or even becomes worse under continued iodine administration. This is a very real and serious problem regarding which, unfortunately, there is no unanimity of opinion. This question also involves the problem of "iodine fastness" or "iodine resistance."

Basal metabolic rates on admission to the hospital.

two-thirds cc. was given each morning. There was no fixed period between the onset of iodine medication and the day of operation. We have operated as early as the fifth day and as late as six weeks after the beginning of iodine medication. The average period of preoperative iodine medication was eleven days. The patients were observed carefully during this period to avoid any complications that might delay surgery, particularly exposure to infections of the upper respiratory tract, to which their susceptibility is extreme and well known. A rapid and good effect from iodine was always considered a good prognostic sign, and failure to respond by a drop in the basal metabolic rate, subsidence of clinical activity or a gain in weight was always viewed with suspicion.

We shall consider at another point the management of this group who fail to respond favorably to iodine. During the period of iodine medication the basal metabolic rate was determined every third or fourth day and the operation performed as soon as the basal metabolic rate fell to plus 30 per cent or less. We wish to emphasize that although we consider the basal metabolic rate the best single indicator of the severity and progress of exophthalmic goiter, we are convinced that it is only one factor and that the disease is a great deal more than an elevated metabolic rate. We have seen

At the outset let us state our position clearly. In general the continuous, or even intermittent, administration of iodine to all patients with exophthalmic goiter over long periods of time is unwise and may even be dangerous. We feel that there is a clear difference in the reaction to iodine of a sufferer from exophthalmic goiter who has never received the element, if compared to one who has been under its effects for some time. One can almost predict a direct, immediate and significant amelioration of the course of the disease if the patient has never been given iodine. This is true whether the illness is of long or short duration, of moderate or severe intensity. Almost all these patients can be quickly improved to a point at which operation is safe. How different is the situation when one is faced by a patient who has had iodine for weeks or months. Experience has taught us how little more we can usually expect from the further administration of iodine. A failure to respond to the standard regimen plus iodine always leads one to suspect previous recent iodination, and this suspicion is often confirmed. We do not pretend to explain this phenomenon, although theories have been advanced (Marine), but the clinical fact is obvious that good responses are the rule in patients who have not had iodine, and are less frequent in iodinated subjects.

We are aware that there are competent observers who have long disagreed with this point of view. These men believe that iodine always consistently lowers the basal metabolic rate and the tempo of the disease and that those cases in which it apparently fails to do so are merely examples of spontaneous alteration in the severity of the disease which would be even more marked if iodine were not administered. As a result of this concept they favor the administration of iodine and still more iodine to patients failing to improve under its use, hoping that the disease will ultimately spontaneously regress and that this regression will be accelerated by the iodine. If this point of view is correct, there should be no essential difference in the reaction of iodinated and uniodinated patients. In fact, we should expect, according to this concept, failure to respond in a considerable number of cases in which the natural tendency of the disease was toward greater severity. This should be true particularly in hospitalized patients, for it is hardly likely that ward patients would regularly seek hospital care while their condition was improving. Yet a study of these cases reveals scarcely a single example of failure to respond favorably to iodine by untreated patients, and frequent failure to respond by iodinated patients. It seems very strange that the "spontaneous" course of the disease was almost always favorable in patients who had received no iodine and unfavorable in iodinated patients. It is our opinion that these alterations were not spontaneous but induced by the iodine and that the iodine was unable to induce the favorable change if it had already been given for a period of time.

It has been our practice to continue the use of iodine for a period of about ten to fourteen days in patients who have received it before admission. If their condition improves sufficiently to warrant operation, this is performed. If this period brings no improvement or if deterioration sets in, we discontinue all iodine for at least six weeks. This sometimes leads to a considerable aggravation of symptoms in the first or second week, and we give heavy sedative medication at that time. After a six weeks period we again use iodine as in our routine and we usually see a direct and favorable response and can proceed with surgery.

SURGICAL CONSIDERATIONS . .

This paper deals with the general management of exophthalmic goiter. For this reason we shall not discuss in detail the finer points of this surgical technic.

In 80 per cent of the cases the operation was finished in one stage; in 20 per cent a two stage operation was performed. In about a dozen cases the originally proposed second stage was not done, as the condition of the patient was very good when seen in the follow-up clinic. In very severe toxic cases the two stage method was definitely planned before the patient came to the operating room. In other cases we were guided in our decision as to the one stage or two stage procedure by the report of the anesthetist or the general behavior of the patient or by encountering exceptional technical difficulties (for instance, excessive bleeding) during the operation.

When in doubt we have employed the two stage procedure. It is impossible to fix definite rules with regard to the question which cases should be selected for the one stage and which for the two stage operation. While some very severe cases of exophthalmic goiter are definitely labeled suitable only for a two stage operation, others are on the borderline. It is perfectly reasonable to assume that we might have achieved just as good results if we had confined the two stage procedure to about 10 per cent of the cases instead to 20 per cent. However, it is very often impossible to predict which cases may present a postoperative crisis. Thus to be on the safe side and to prevent if possible this alarming and usually fatal complication, we have selected the two stage operation when in great doubt.

There are several different methods for thyroidectomy. Some surgeons split both ribbon muscles; others get a good view of the operative field by simple retraction of these muscles. In this series the right ribbon muscles were usually divided. After the right lobe had been resected following the ligation of the right polar vessels and division of the isthmus, it was easy to dislodge the left lobe from its bed and proceed to the resection of the left lobe without division of the left ribbon muscles. Minute and careful hemostasis is of the utmost importance. We have usually drained the operative field and were thus able to minimize the postoperative collection of serum in the wound.

The patient is moved from the operating room to the surgical wards; not into the large ward, however, but into an adjacent small room for one or two patients. Except in very mild cases special nurses (day and night) supervise the postoperative treatment during the first one to three days. Immediately after the operation and during the next few days the patient is visited at frequent intervals by the medical and surgical staffs. Staff visits should not, however, be paid indiscriminately in order to avoid interference with the patient's rest. The room is kept dark and quiet. No visitors are allowed during the first few days. The patient is given plenty of fluid. A tracheotomy set and a suction apparatus are at the bedside. The suction apparatus is used to prevent the collection of mucus in the pharynx. Catheterization is done every ten hours unless the patient voids spontaneously. Methenamine and acid sodium phosphate are given if catheterization is necessary. The patient receives 6 minims (0.4 cc.) of Magendie's solution every six hours. The nurse is instructed to watch for and report to the house surgeon any bleeding, cyanosis, dyspnea or swelling of the face or neck. The total intake of fluid and output of urine

are charted. A steam inhalation apparatus is kept at the bedside; two-thirds cc. of compound solution of iodine is given as soon as the patient reacts. If a patient has not reacted after five hours, the compound solution of iodine is given by rectum. The patient receives an additional 2 cc. of compound solution of iodine in 1 ounce of water by mouth during the first twelve hours. If this is vomited, another dose is introduced by rectum. After the second day the compound solution of iodine is reduced to two-thirds cc. a day. The temperature is taken immediately after arrival from the operating room and every four hours thereafter. A rise of temperature above 102 F. and a rise of pulse rate above 130 beats a minute must be reported immediately by the nurse.

If any alarming symptoms occur, both medical and surgical attendants are immediately notified by the house surgeon and respond for a consultation. We feel that this close cooperation between the two staffs has been of great help to the patient and has improved our results considerably.

Naturally, the operations were performed by a number of surgeons. In fact, we are presenting the combined results of thirteen different surgeons. The majority of the patients (247) were operated on by the attending surgeon or by one of his two associate surgeons; the rest (113 patients) were operated on by ten adjunct surgeons. In this hospital we have the group system in the surgical service. The junior surgeons rotate among these groups, staying one year in each group. Naturally their experience in this special thyroid group is limited. For this reason one of the senior members of the staff assisted them at the operation. No patients with exophthalmic goiter were turned over to the house surgeons for operation.

No polar ligations were performed in this series. Undoubtedly polar ligation in the group of very sick patients is not without risk. It seemed to us that polar ligation is of no benefit because of the abundant blood supply which still reaches the thyroid gland after one or even both upper thyroid poles have been ligated. If thyroidectomy is performed in two stages, the patients are informed before they leave the hospital for a two or three weeks stay in the country that they are to return for a second operation. They stay on compound solution of iodine during the interval between the two stages. They are readmitted to the hospital directly from the convalescent home. It is inadvisable to have them return to their homes before they reenter the hospital. In the vast majority of cases such a stay at home would mean emotional shock and hard work (cooking, looking after the children and the like). We have had very little difficulty in enforcing the two stage operation. Only a few patients absolutely refused the second stage. None of this small group presented a satisfactory result when reexamined in our follow-up clinic, demonstrating the importance of a complete operation in order to effect a cure.

NONSURGICAL CASES

During the period of this study we observed forty-seven patients with definite exophthalmic goiter who, for one reason or another, did not come to operation. Of these patients, nine died while in the medical service, and a brief analysis of these deaths will be given. We offered operation to eighteen others who refused and left the hospital at their own request. There were eight patients who presented such a mild form of the disease that we did not consider surgery to be indicated. All these made complete recoveries under medical treatment. Three patients became psychotic with suicidal

tendencies while in the hospital and had to be transferred to a psychiatric institution. The remaining nine cases, after study by the medical group, were considered unsuitable for surgery and were treated medically. In one case there was a difference of opinion between the medical consultants—one favored surgery and the other opposed it. In this instance the surgeon refused to operate. We refused to operate on another patient aged 69 whom we considered too poor a risk. She was given compound solution of iodine and roentgen therapy and was quite well, with a basal metabolic rate of minus 16 per cent, four years later.

Of the nine deaths among patients who were still in the medical service, six occurred within three weeks of admission. All these patients were desperately ill on admission to the hospital, and most of them were of the older age group who had serious cardiovascular complications. One patient died of an acute coronary artery thrombosis complicating diabetic ketosis. The remaining two patients died in typical thyroid storms following respiratory infections.

POSTOPERATIVE COURSE

Naturally in a series of more than 500 operations some postoperative accidents are apt to occur. A very small number of postoperative hemorrhages were seen. When such hemorrhage occurred, the patients were immediately taken back to the operating room where we had an opportunity to inspect the operative field carefully and stop the hemorrhage.

We did not observe any case of tetany of more than the lightest grade or of more than passing duration. As the symptoms never lasted more than from thirty-six to forty-six hours, we assumed that they were caused by a temporary injury to the parathyroids due to application of the clamp during the removal of the thyroid gland rather than to ablation of a part of one or more parathyroids.

MORTALITY

There were three deaths among 460 patients operated on for the first time for their thyroid disease. One of these deaths cannot be considered as an operative mortality. The patient had a subtotal thyroidectomy performed in two stages. The second stage was done after an interval of four weeks, during which the patient was kept in this hospital. She had reacted well after the second stage of the operation and had a comfortable night. The following day, while a special nurse left the room for a few minutes, the patient jumped out of the window and was killed immediately. The patient's husband told us later that she had played with the thought of suicide for many months. He had never taken her seriously and so had never mentioned the subject to us.

There was no mortality among the nontoxic group, in spite of the fact that some of these cases presented serious technical problems (large intrathoracic goiters and retrotracheal and retro-esophageal goiters). For instance, in one case of retrotracheal goiter the trachea was divided on its posterior aspect. The wide opening was immediately sutured and the patient made an uneventful recovery.

If we consider the operative deaths in the previously unoperated exophthalmic goiter group, we had a mortality of 0.5 per cent, if the case of suicide is not included.

There were two deaths among the twenty-six patients operated on for recurrent exophthalmic goiter. Both patients had had exophthalmic goiter for many years

and were extremely poor operative risks. In one case the operation (hemithyroidectomy) was performed under local anesthesia, as general anesthesia was definitely contraindicated because of the precarious general condition of the patient. In the other case a primary operation had been performed about twenty years previously at another hospital. In this case the heart was of the bovine type and the roentgenograms demonstrated the extreme risk of any operation in view of the serious cardiac changes. Yet the medical service felt that an attempt at relief by surgery should be made.

Among these twenty-six secondary cases operation had been performed in other hospitals in thirteen. Ten patients had had their first operation in this hospital many years before, and three had both their primary operation and their operation for recurrence during the period of this study.

FOLLOW-UP OBSERVATIONS

The close cooperation between the medical and surgical staffs in the management of goiter cases was continued in the follow-up observation of these patients. Members of both groups met twice a month in the thyroid follow-up clinic, where about thirty patients were seen at each session. The follow-up clinic worked in close cooperation with members of the thyroid clinic of the outpatient department (Dr. Benjamin Eliasoph and his staff, including a social service worker). The patients were seen by appointment. If necessary they were sent for further study to the thyroid clinic and referred back to the follow-up clinic with a detailed report and careful check up. Thus we were able to follow up 248 of our 360 patients and to classify them into three groups, according to the final results: group 1 (good), 225 cases; group 2 (fair), nineteen cases; group 3 (poor), four cases. The subsequent course of the remaining 112 patients could not be ascertained because contact with them had been lost.

Any grouping is subject to individual and personal impression. This factor, however, was minimized as the category to which a patient was assigned was decided by a number of physicians and not solely by the operating surgeon.

We have often been asked about our position toward x-ray treatment of exophthalmic goiter. We are opposed to this form of treatment in primary exophthalmic goiter. We have rarely seen a definite cure following x-ray or radium therapy. When improvements are seen following roentgen therapy, one is uncertain whether to ascribe this to a remission in the disease rather than to a specific effect of the x-ray treatment. Furthermore, any subsequent operative procedure is probably rendered more difficult, owing to a tendency to excessive bleeding and marked periglandular adhesions. However, in a few relapsing cases, especially when the symptoms are caused by a small mass of recurrent or persistent thyroid tissue, we have seen some very good results from x-ray therapy.

SUMMARY

1. Of the 460 patients with thyroid disease not operated on previously, who were treated surgically from April 1, 1932, to April 1, 1937, 360 cases belonged to the toxic group and 100 cases were nontoxic.

2. The mortality (three cases) occurred in the toxic group.

3. The mortality (including one suicide) was 0.8 per cent among the primary cases of exophthalmic goiter.

4. Operative deaths numbered two (0.5 per cent) among the primary cases.

5. There were two operative deaths among twenty-six cases of recurrent exophthalmic goiter.

6. Twenty per cent of the patients were operated on in two stages.

THE ONE HOUR-TWO DOSE DEXTROSE TOLERANCE TEST (EXTON-ROSE PROCEDURE)

DIAGNOSTIC SIGNIFICANCE

MORGAN W. MATTHEWS, M.D.

Fellow in Medicine, the Mayo Foundation

THOMAS B. MAGATH, M.D.

AND

JOSEPH BERKSON, M.D.

WITH THE ASSISTANCE OF ROBERT P. GAGE

ROCHESTER, MINN.

The present study is a part of a survey¹ of dextrose tolerance tests of various types used in the Mayo Clinic between Nov. 1, 1935, and June 30, 1938, inclusive. The present report is confined to the analysis of results obtained with the one hour-two dose test introduced in 1931 by Exton and Rose.² A criterion for interpreting this test is presented which in our experience has given fewer doubtful laboratory diagnoses than could be obtained by other criteria applied in this test, or by any criteria applicable in other oral tests for dextrose tolerance.

Following the discovery of chemical procedures by which the presence or absence of sugar in the urine can be accurately determined, it was noted that glycosuria cannot be constantly demonstrated in patients with mild diabetes. In them glycosuria was found most frequently to follow the ingestion of certain foodstuffs, notably those that contain a high percentage of carbohydrate. Tests utilizing the principle of this observation were then introduced, with the hope that normal and diabetic individuals could be differentiated from one another by this means. An individual in whom diabetes was suspected was given an amount of carbohydrate ranging from 50 to 200 Gm. The urine was then examined at varying intervals for the presence of sugar. The discovery of glycosuria was thought sufficient to warrant a diagnosis of diabetes. This method, however, soon fell into popular disrepute because the ability of both normal and diabetic individuals to handle carbohydrate was subject to such wide variation that the test was unreliable. The objections to the method have been well summarized by Allen³ and by Hamman and Hirschman.⁴

The work of MacGregor, of Rollo and Ambrosini, of Bang and of Jacobson has been cited by Bailey.⁶ In 1856 the dependence of glycosuria on an increase of the concentration of sugar in the blood above the normal level was recognized by MacGregor and by Rollo and Ambrosini. The methods of analysis advocated by these workers were so complicated and inaccurate that dependence could not be placed on their observations. Bang in 1913 introduced the first satisfactory and clinically applicable method for the accurate determination of the blood sugar level. Jacobson in the same year noted that the ingestion of carbohydrate is followed by a rapid and often marked hyperglycemia. Fat and protein were found to produce no particular variation in the blood sugar level. These observations suggested to Hopkins,⁶ to Janney and Isaacson⁷ and to Hamman and Hirschman that the administration of carbohydrate followed by frequent determinations of the blood sugar might be used to determine the ability of an individual to handle carbohydrate. The use of such carbohydrates

Chart 1.—Average blood sugar value (in milligrams per hundred cubic centimeters of blood) of members of this study.

as bread, crackers and oatmeal gruel as the test substance gave disappointing results. Apparently these products were broken down into their component food elements so slowly that their subsequent absorption from the intestinal tract imposed a metabolic strain on only those patients in whom a serious derangement of carbohydrate metabolism was present. Mild or even moderately severe cases of diabetes were frequently considered to have a normal metabolism for carbohydrate when this method was used.

Hamman and Hirschman in 1917 and Janney and Isaacson in the following year independently introduced dextrose as the test substance for determining the individual's ability to tolerate carbohydrate. The methods advocated by these two groups of observers differed only in the amount of dextrose that was administered. The former proposed the use of a standard amount of

dextrose, namely 100 Gm., while the latter advocated the use of dextrose in proportion to the number of pounds of body weight. The amount that was found to be most satisfactory was 1.75 Gm. of dextrose per kilogram of body weight. These two methods constitute essentially what is now known as the standard dextrose tolerance test. That this test has not proved a completely satisfactory procedure is demonstrated by the number of modifications that have at one time or another been proposed. It is not our purpose in this paper to enter into a discussion of all these various modifications. However, a comparatively recent modification of the test by Exton and Rose has gained widespread popularity, and it is with this modification that we here are primarily concerned.

The Exton-Rose procedure is based on what is known as Allen's⁸ paradoxical law of dextrose utilization. Briefly stated, the law is: The more sugar that is given to a normal individual, the more that is utilized. Limits of tolerance in nondiabetic individuals⁹ are all apparent, not real. There is no real limit to the ability of a normal person to utilize dextrose. In contrast, the inability of the person suffering from diabetes to handle dextrose is real. Large doses of sugar in these individuals are not utilized and assimilation may be made worse instead of better by overdosage. Exton and Rose, on the basis of this law, formulated the one hour-two dose dextrose tolerance test, or, as it is perhaps better known, the Exton-Rose procedure.

The technic of the test is as follows: One hundred Gm. of dextrose is dissolved in 650 cc. of water, making approximately a 15 per cent solution. This solution is flavored with lemon juice and is divided into two equal parts, each containing 50 Gm. of dextrose. The mixture is served cold. Following an overnight fast the bladder is emptied as completely as possible, and then the following steps are taken: (1) samples of blood and urine are collected and the first dose of dextrose is given, from one to two minutes being allowed for its ingestion; (2) thirty minutes after the ingestion of the dextrose a second sample of blood is collected and the second dose of dextrose is given, from one to two minutes being allowed for its ingestion, and (3) thirty minutes after the ingestion of the second dose of dextrose a third sample of blood and a second sample of urine are collected.

There is much physiologic research that supports the contention that the Exton-Rose procedure is based on sound physiologic principles. Hamman and Hirschman,¹⁰ MacLean and de Wesselow,¹¹ Hansen,¹² Foster,¹³ Lennox¹⁴ and Hale-White and Payne¹⁵ found that, if successive doses of dextrose are given

9. This applies only to dextrose administered by mouth. Given intravenously, tolerance for dextrose is very definitely limited by the rate of administration, as was demonstrated by Blumenthal (quoted by Woodyatt, Sansum and Wilder) and later, with more precision of method, by Woodyatt, Sansum and Wilder (Prolonged and Accurately Timed Intravenous Injections of Sugar, J. A. M. A. 65: 2067-2070 [Dec. 11] 1915; Disease, Arch. Int. Med. 19: 311-334 [Feb.] 1917).

to man or animal on the same day, the second blood sugar curve reaches a peak at a lower level than the first curve, the third curve lower than the second, and so on. In the United States the phenomenon has come to be known as the Hamman-Hirschman effect; in Germany as the Staub¹⁶-Traugott¹⁷ phenomenon. Thalhimer, Raine, Perry and Buttles¹⁸ observed a rise in the blood sugar during the first hour in which 10 per cent solution of dextrose was given intravenously. Although the injection was continued at the same rate, the blood sugar level during the second hour declined progressively. Following the injection, hypoglycemic levels were often reached and in some cases symptoms of a mild hypoglycemic reaction were experienced.

The common explanation of the phenomena cited in these experiments is that carbohydrate stimulates the pancreas to produce more insulin and by repeated stimulation so much insulin is produced that the excessive amount causes hypoglycemia. Soskin and his co-workers¹⁹ have attacked this conclusion and, on the basis of a series of experiments on dogs, have maintained that the pancreas is not essential for such a reaction. On the other hand Ricketts,²⁰ also on experimental grounds, has challenged Soskin's interpretations. Without denying that the liver may play an independent part in the regulation of the blood sugar, the experiments of Ricketts indicate, he concluded, that the proper functioning of the liver under normal circumstances depends on the availability of an extra supply of insulin by the pancreas at the time of ingestion of carbohydrate.

The principal advantages of the Exton-Rose test over the standard test of tolerance for dextrose are as follows: 1. The shorter duration of the test tends to diminish the influence of certain external factors, such as hunger, anxiety, emotion, fatigue and impatience, on the character of the tolerance curve. Exton and Rose concluded that no more information as regards carbohydrate utilization could be obtained if the test was extended over a longer period than one hour. 2. Fewer venipunctures and fewer chemical determinations are necessary than under the standard test.

ANALYSIS OF RESULTS OBTAINED WITH THE EXTON-ROSE TEST OF TOLERANCE FOR DEXTROSE

In the present study a statistical analysis has been made of the results of the Exton-Rose procedure in a group of 117 individuals that were considered to have a normal tolerance for carbohydrate, a series of 304 individuals with diabetes that had been clinically graded according to the severity of the disease, and a series of seventy persons for whom the clinical diagnosis was renal glycosuria. In all three of these arbitrary classifications we have eliminated all cases with an associated condition, other than the disease diabetes, that might possibly influence the effect of ingested dextrose on the level of the blood sugar.

The diagnosis in some of these cases may not have been correct. On the contrary, being based on clinical

judgment, it was necessarily subject to error. Some sort of classification was necessary, however, and as each diagnosis was based on a thorough study of all aspects of each case by clinicians with special experience in diabetes²¹ it was considered the best basis available. An important part of this study consisted in a comparison of the blood sugar level during the various phases of the reaction with the clinical diagnosis previously recorded. It will occur to one that there is an element of circularity involved, for it may be said that the clinical diagnosis was based on the blood sugar observations. The objection is not as serious as it might appear to be. In the first place the clinical diagnoses were by no means based on blood sugar determinations alone but were made on clinical observations in conjunction with all laboratory examinations. Secondly, our conclusions, as will appear, are in favor of criteria other than those that were used to interpret the results of the Exton-Rose tests at the time the diagnosis was made, for these criteria are in fact a result of this study.

All patients with diabetes in the Mayo Clinic receive a clinical grading depending on the severity of the disease. An individual is said to have latent diabetes or

All forms of diabetes	304	127.0	68-572	211.3	111-608	270.1	154-770

diabetes grade 1 if the urine can be maintained free from sugar on a qualitatively restricted diet. It is very doubtful if any one could distinguish clinically, or by any other method that we now have, between latent diabetes and diabetes grade 1. The term latent diabetes is reserved for the mildest form of the disease seen in practice. In most of these cases a dextrose tolerance test is necessary to establish the presence of the disease. Grade 2 diabetes exists if a weighed diet providing adequate calories and containing not more than 200 Gm. of carbohydrate is necessary to control the glycosuria. Grade 3 diabetes is said to be present if, in addition to such a weighed diet, 30 units or less of insulin each day is necessary to maintain the urine free from sugar. Grade 4 diabetes is diabetes that requires such a weighed diet and an amount of insulin greater than 30 units each day for its control.

Statistical analyses of the means and range of the blood sugar determinations during the various phases of the Exton-Rose procedure are summarized in table 1 and are presented graphically in chart 1.

The fasting blood sugar in those individuals whose carbohydrate metabolism was considered normal ranged from 63 mg. to 110 mg. per hundred cubic centimeters of blood. Only five persons had a fasting blood sugar that exceeded 100 mg. and in but one of these did the fasting blood sugar reach a height of 110 mg., which was the maximal concentration in the series. In contrast the fasting blood sugar readings for the persons

with latent or grade 1 diabetes ranged from 68 mg. to 234 mg. per hundred cubic centimeters of blood. Only 21 per cent of the members of this group had fasting blood sugar determinations that exceeded 120 mg. There was a 70 per cent overlap of the fasting blood sugar readings of the diabetic group into the range of the normal series (chart 2).

Chart 2.—Distribution of fasting blood sugar readings in 117 normal individuals and 247 persons with latent or grade 1 diabetes.

The average blood sugar level at any time point of the test is progressively elevated as one ascends the scale from normality and mild diabetes to the severer forms of the disease. In normal individuals and persons with renal glycosuria the rise in the blood sugar one-half hour after dextrose has been given is noted to be moderate when compared with the average rise that occurs in diabetes during the same period. The characteristic rise-fall reaction of the concentration of sugar in the blood of normal individuals and persons with renal glycosuria at the half hour and one hour points respectively is evident. The only significant distinction between normal individuals and persons with renal glycosuria as far as the tolerance test is concerned is the excretion of sugar in the urine by members of the latter group. In the various grades of diabetes the rise-fall reaction is absent, the average blood sugar value at one hour being higher than the average blood sugar value at the half hour reading. The importance of this observation will be referred to later.

TABLE 2.—Age Distribution: Average Blood Sugar Values During the Various Phases of the Reaction in Normal Individuals and Persons with Latent and Grade 1 Diabetes

Age, Years	Num-ber of Cases	Normal			Num-ber of Cases	Latent and Grade 1 Diabetes

Many investigators have reported a progressive elevation of the tolerance curve with advancing age. An analysis of our data supports this conclusion. Table 2 shows for the normal and grade 1 diabetic groups the effect of advancing age on the blood sugar values at the various phases of the reaction. It is seen that for all determinations, the fasting, half-hour and hour readings, the concentrations of sugar in the blood progressively increase with age.

The next step in our analysis was to apply the criteria that have been proposed by Exton and Rose and

also those of Gould, Altshuler and Mellen²² to the group of 117 normal individuals and 247 persons with latent or grade 1 diabetes. The criteria of Exton and Rose are:

A. *Normal tolerance curve:*

1. A fasting blood sugar within the normal limits of the particular blood sugar method employed.
2. A rise in the blood sugar which does not exceed 75 mg. in the thirty minute sample.
3. The blood sugar in the sixty minute sample is less, the same, or does not exceed the thirty minute sample by more than 5 mg.
4. All urine samples are negative to the Benedict test.

B. *Diabetic tolerance curve:*

1. A more or less steep curve of not less than 10 mg. of blood sugar following the second dose of dextrose.
2. The relation of the blood and urine sugar values to the severity of the disease.

C. *Renal glycosuria tolerance curve:*

1. Blood sugars which follow the normal tolerance curve or in any event never reach the diabetic level.
2. Sugar in both urine specimens.

D. *Alimentary glycosuria tolerance curve:*

1. Blood sugars that follow the normal curve even when the level is higher than normal.
2. A sugar-free urine after fasting, with sugar in the final urine specimen.

TABLE 3.—Comparison of Criteria When Applied to 117 Clinically Normal Individuals and 247 Persons with Latent or Grade 1 Diabetes

Diagnosis According to Criteria	Normal Individuals Diagnostic Criteria Applied				Latent and Grade 1 Diabetes Diagnostic Criteria Applied			
	Exton-Rose		Gould et Al.		Exton-Rose		Gould et Al.	
	Num-ber	Per Cent	Num-ber	Per Cent	Num-ber	Per Cent	Num-ber	Per Cent
Normal.....	85	72.7	75	64.1	1	0.4	1	0.4
Diabetes.....	22	18.8	236	95.5	191	77.3
Nondiagnostic.....	10	8.5	42	35.9	10	4.1	55	22.3
Total.....	117	100	117	100	247	100	247	100

According to our interpretations of these criteria, if the fasting blood sugar is within normal limits and if the one hour reading does not exceed the half hour value by 10 mg. or more, even though the half-hour blood sugar determination is as high as 245 mg., the case cannot be considered as diabetic. It would seem that such a reaction is definitely abnormal and the possibility of diabetes should be seriously considered. Apparently but one requisite is necessary according to the criteria of Exton and Rose for a diagnosis of diabetes, and that is that the hour blood sugar determination should exceed the half hour reading by 10 mg. or more. If this condition is not fulfilled and the fasting blood sugar exceeds 120 mg., the case can be considered neither diabetic nor normal, and therefore the tolerance curve must be nondiagnostic. When the rise in the blood sugar one hour after the ingestion of the first dose of dextrose lies between 5 and 10 mg. above the half hour reading, again it must be called nondiagnostic. A curve that has a half hour blood sugar reading that is more than 75 mg. higher than the fasting value, while the other values of the curve are within normal limits, according to the criteria must be called alimentary hyperglycemia.

22. Gould, S. E.; Altshuler, S. S., and Mellen, H. S.: The One-Hour Two-Dose Glucose Tolerance Test in the Diagnosis of Diabetes Mellitus, *Am. J. M. Sc.* 193: 611-617 (May) 1937.

The criteria of Gould, Altshuler and Mellen are:

A. *Normal tolerance curve:*

1. The fasting blood sugar is less than 120 mg.
2. The half hour level is less than 50 mg. above the fasting value.
3. The level of the blood sugar at one hour is less than 30 mg. above the half hour value.

B. *Diabetic tolerance curve:* The presence of only two of the following three conditions indicates diabetes:

1. A fasting blood sugar of 120 mg. or over.
2. A half hour level of 50 mg. or more above the fasting value.
3. A one hour level of 30 mg. or more above the half hour level.

The difficulties that these criteria encounter are at once evident. Two out of the three criteria noted must be present in order to diagnose diabetes. Even if the fasting blood sugar level were grossly abnormal, say 400 mg. per hundred cubic centimeters of blood,

Total.....	364	321	88.2	266	73.1

TABLE 5.—*Effectiveness of Blood Sugar Levels as Criteria for Designating Cases in Agreement with Clinical Diagnosis*

Blood Sugar Reading	Critical Values of Blood Sugar (Mg. per 100 Cc. Blood)		Correctly Diagnosed by Criteria of Blood Sugar Level					
			117 Normal		247 Diabetic		364 Total Cases	
	Normal	Diabetic	Num-ber	Per Cent	Num-ber	Per Cent	Num-ber	Per Cent
	Fasting blood sugar	Less than 90	90 or more	74	63	218	88	292
½ hour blood sugar	Less than 142	142 or more	68	75	237	96	325	89
1 hour blood sugar	Less than 158	158 or more	111	95	247	100	358	98

if the half hour reading was less than 50 mg. above this figure and the hour reading was less than 30 mg. above the half hour determination the case could be called neither normal nor diabetic. Such a tolerance curve must therefore be nondiagnostic. The same reasoning applies when the half hour blood sugar reading exceeds the fasting level by more than 50 mg., while the two other values are within the normal limits that are specified by the criteria. Similarly, if the blood sugar at the one hour determination is 30 mg. or more above the half hour value, while the other readings are within the limits of normal as defined by the criteria of these investigators, the curve is again nondiagnostic. Gould and his collaborators do not consider the diagnosis of renal glycosuria and alimentary hyperglycemia. When we apply their criteria we shall consider renal glycosuria as a normal tolerance curve with glycosuria. An alimentary hyperglycemia type of curve fulfils only one of the three criteria, two of which are necessary for the diagnosis of diabetes, and cannot be considered as normal because it exceeds the 50 mg. rule of the half hour reading; it must therefore be called nondiagnostic. With such a variety of confusing combinations we should expect such criteria to yield a large percentage of nondiagnostic tolerance curves.

Tables 3 and 4 summarize the results of designating the normal and diabetic series according to the criteria of Exton and Rose and of Gould and his co-workers. It is seen from table 3 that, considering the 117 individuals clinically diagnosed as nondiabetic, 73 per cent were diagnosed normal by the Exton-Rose criteria and 64 per cent by the criteria of Gould and his co-workers.

TABLE 6.—*Distribution of the One Hour Blood Sugar Readings in 117 Normal Individuals and 247 Persons with Latent or Grade 1 Diabetes*

Of the 247 individuals in the diabetic series, 96 per cent were designated diabetic by the Exton-Rose criteria and 77 per cent by the criteria of Gould and his co-workers. In table 4 we see that, considering the entire series of 364 individuals, the application of the Exton-Rose criteria yielded diagnoses in agreement with clinical diagnosis in 88 per cent of the cases, while that of the criteria of Gould and his co-workers yielded 73 per cent in agreement with the clinical diagnosis.

It appeared to us on the basis of general observations of the level of the blood sugar at the fasting, half hour and hour points that a better differentiation between normal subjects and persons with diabetes might be made by considering the level of the blood sugar itself rather than the change of the value from one time to the next. Since each observation is necessarily subject to variation and error, the difference

Chart 3.—*Distribution of the one hour blood sugar readings in 117 normal individuals and 247 persons with latent or grade 1 diabetes.*

between two observations, say, at the half hour and hour points, is, a priori, subject to more variability than the values themselves, though this is not necessarily true. At any rate we undertook to make an objective examination on the basis of the absolute values of the blood sugar determinations at each phase of the tests (table 1, chart 1). We decided to use as a criterion to demarcate normal individuals from persons with latent diabetes a value of the blood sugar half

way between the mean values for the particular point in the test. Thus, utilizing the fasting blood sugar as a criterion, the mean value for the normal group was 84.6 mg. per hundred cubic centimeters and the mean value for the latent diabetic group was 94.5 mg.; averaging these two groups, the figure of 90 mg. is obtained. Accordingly we reasoned that an individual who had a fasting blood sugar in excess of 90 mg. would be more likely to be diabetic. Conversely, a fasting blood sugar below 90 mg. would be more indicative of a normal tolerance for carbohydrate. Similarly, a half-hour blood sugar value of 142 mg. and an hour reading of 158 mg. were selected as critical levels. The results of applying these criteria to the 117 normal individuals and the 247 persons with latent or grade 1 diabetes are shown in table 5.

In table 5 it is seen that, using the fasting blood sugar alone, 63 per cent. of the normal persons and 88 per cent of the persons with diabetes would have been designated in agreement with the clinical diagnosis, giving for the entire series of 364 cases 80 per cent designated in agreement with the clinical observations by the criterion of the fasting blood sugar level alone. If the half-hour blood sugar reading is employed for the entire series, it is seen that 89 per cent were designated in agreement with the clinical diagnosis. If the hour reading of the blood sugar is used, 95 per cent of the normal persons were designated in agreement with the clinical findings and all the patients with diabetes were so designated, making, for the entire series, a designation of 98 per cent in agreement with the clinical diagnosis. This very close agreement, using the simple criterion of the level of the blood sugar at the hour reading, is due to the fact that according to the observations in our series the distribution of the hour reading is widely divergent in the normal and diabetic groups. This is shown by table 6 and chart 3.

It may be emphasized again that the criterion of the value of the blood sugar at the hour reading could not have been the one employed in making the clinical diagnosis in these cases, since this criterion was developed in the course of this study after all the clinical diagnoses had been designated in the histories.

COMMENT

The finding that the value of the blood sugar at a particular time point (one hour) of the curve obtained in a one hour-two dose test of dextrose tolerance has diagnostic significance of importance is in harmony with the observations of Hansen,²³ who emphasized that the normal organism has the capacity to accelerate the removal of sugar from the blood at times when values for blood sugar would otherwise rise abnormally. A result of such regulation is the establishment of a definite upper limit or blood sugar ceiling, called by Hansen the "optimum concentration." This upper limit, when dextrose is introduced into the blood stream at a rate no greater than is possible by absorption from the bowel, is normally never exceeded. Furthermore this upper limit, as Hansen has shown, is nearly the same value as that of the renal threshold for dextrose, which explains why glycosuria is avoided no matter how much sugar is ingested by normal persons. In such persons the highest values attained by the blood sugar after the ingestion of as much as 400 Gm. of dextrose were found by Hansen to lie between 160 and 180 mg. per hundred cubic centimeters.

Other causes of hyperglycemia being absent, a disturbance of the ability of the organism to prevent elevation of the blood sugar above what Hansen called the "optimum concentration" ought to represent a criterion of diabetes mellitus. This is exactly what is revealed by the blood sugar reading at one hour in a test like that of Exton and Rose. The amount of dextrose administered by mouth in such a test must be large enough to effect a maximum rate of absorption from the bowel at the time (one hour) blood is taken for analysis, but the amount provided in the Exton-Rose test is ample. According to Hansen as great an elevation may be obtained with 50 Gm. as with 200 or 400 Gm.

It is possible that the one hour reading of the blood sugar would be equally significant diagnostically if all the dextrose (100 Gm.) was ingested at the zero hour instead of in the two doses, each of 50 Gm. at half hour intervals, as called for in the Exton-Rose procedure. Dividing the dose is helpful, however, because it avoids an unpleasantly large dose at one time. It also is not improbable that the second dose, given thirty minutes after the first, increases the divergence of the one hour blood sugar values because of a Hamman-Hirschman (Staub-Traugott) effect in cases without diabetes. This may explain the greater diagnostic significance of the value of the blood sugar at one hour in the Exton-Rose test over that at thirty minutes.

In view of these considerations we are not suggesting any change in the procedure of the tolerance test of Exton and Rose and have limited our comments to the interpretation of the values for blood sugar obtained with the test as originally described. Our results do suggest, however, that the test may be simplified without loss of reliability by the omission of two of the three samplings of blood originally called for, namely the one before the dextrose is given and the one at thirty minutes.

CONCLUSIONS

1. Advancing age produces a progressive elevation of the blood sugar level at every phase of the blood sugar time curve obtained with the dextrose tolerance test of Exton and Rose. The degree of this, however, is insufficient to invalidate conclusions 2 and 3.

2. A fasting blood sugar that exceeds 120 mg. per hundred cubic centimeters of blood is diagnostic of diabetes. This value, however, was exceeded by only 21 per cent of the persons with diabetes in this series of cases in which diabetes was minimal. In contrast, no person in whom the carbohydrate tolerance was considered normal had a fasting blood sugar that exceeded 110 mg.

3. According to our experience, the most effective criterion, with the Exton-Rose procedure, for differentiating persons suffering from diabetes and normal persons is the hour value of the blood sugar. If 158 mg. per hundred cubic centimeters of blood is taken as the critical level so that individuals showing a blood sugar reading below this level at the hour are designated nondiabetic and individuals with readings at or above this value are designated presumptively diabetic, a high percentage of correct diagnoses can be expected. As far as the observations in this series are concerned, all individuals with values at the hour less than 154 mg. were found to be normal, and all individuals with values at the hour of 180 mg. or more were found to be diabetic. Hence these two groupings are most definite. Individuals with values at the hour between 158 and 179 mg. inclusive constituted only a small fraction of our cases (six, or 5.1 per cent, of 117 patients con-

sidered to be nondiabetic and nineteen, or 7.7 per cent, of 247 patients considered to have latent or mildest diabetes). The number of cases with a doubtful laboratory diagnosis was smaller by this criterion than by any other criterion applied to the results of the Exton-Rose test. It also was smaller than that obtained by any criteria applied to the interpretation of other oral tests for dextrose tolerance with which we have had experience.²⁴

THE ROENTGEN ANATOMY OF THE SMALL INTESTINE

GEORGE W. CHAMBERLIN, M.D.

PHILADELPHIA

Anatomically, the small intestine is a convoluted tube which begins in the upper part of the abdomen just distal to the pylorus and ends at the ileocecal valve. Roentgenologically, it is a highly active and dynamic organ with certain characteristic anatomic and physiologic features. Normal roentgen morphology is, for the most part, dependent on muscular tone, physiologic motion, mucosal pattern or a combination of these three factors.

Fig. 1.—The lumen of the small intestine diminishes from above downward. This shows the roentgenologic appearance of the duodenum, jejunum and ileum.

The length of the small intestine is variable. At autopsy it may measure from 5 to 7 meters. Intubation by measured length of tubing has indicated a length of

from 2.5 to 3 meters from the pylorus to the cecum. Such figures, however, may not be accurate because the intestine may telescope itself along the course of the tube and thus produce abnormal shortening. It is generally assumed that the upper three fifths of the

Fig. 2.—The normal mucosal pattern in the jejunum is herring bone or reticular.

mesenteric small intestine is jejunum and the lower two fifths is composed of ileum. On the basis of embryologic and roentgenologic data, Cole¹ has described six primary coils of small intestine. The first coil is the duodenum, while the remaining five groups comprise the ileojejunum, or mesenteric small intestine. In my experience, many variations in the appearance of these coils have occurred.

In 1936 Pendergrass and his associates² stressed the importance of a standard type of meal for the study of the small intestine. The meal that I have used is made of 5 ounces of distilled water and 5 ounces of barium sulfate. Water is distilled to remove the chlorine, which may produce a disturbance in the roentgen appearance of the intestinal tract. A standard preparation of barium sulfate has been found to be quite satisfactory. Recently I compared this usual preparation with a meal composed of water and more finely divided barium. A striking difference in the small intestinal pattern and motility was found when these two meals were studied in the same patient.

Factors such as the composition, size and consistency of the meal, speed of gastric emptying, drugs, emotional disturbances, disease and reflex disturbances from disease outside the gastrointestinal tract are capable of producing changes in the roentgen appearance of the small intestine. In this presentation the discussion will be limited to the roentgen anatomy as seen in healthy subjects.

2. Pendergrass, E. P.; Ravdin, I. S.; Johnson, C. G., and Hodes, P. J.: Studies of the Small Intestine: Effect of Foods and Various Pathologic States on Gastric Emptying and Small Intestinal Pattern, Radiology 26: 651-662 (June) 1936.

24. The analytic technic used in the examinations for concentration of blood sugar was that of Folin and Wu, and all specimens of blood were obtained from the vein. For other methods of analysis or for blood taken for analysis from arteries or capillaries, the values for blood sugar accepted here as criteria for diagnoses would be modified. It also must be emphasized that the diagnostic significance of any values for blood sugar will be modified by all the various conditions, other than the presence or absence of the disease diabetes, that are known to modify blood sugar time curves. Such conditions include previous fasting, preceding diets low in carbohydrate and complications such as infection and hyperthyroidism.

From the Department of Radiology of the Hospital of the University of Pennsylvania.

Read before the joint meeting of the Section on Gastro-Enterology and Proctology and the Section on Radiology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 19, 1939.

In the normal controls that I have studied, the head of the meal reaches the cecum in from one and a half to three hours. The small intestine is completely empty in from five to six hours. The caliber of the lumen diminishes from above downward (fig. 1). Roent-

Fig. 3.—Note the longitudinal folds in the duodenal cap and the coarse, reticular pattern of the remainder of the duodenum. The duodenal stream is intermittent.

genologically, one can distinguish duodenum, jejunum and ileum, although the line of demarcation between them is not well defined. The duodenum, which begins just distal to the cap at the first circular fold of mucosa, is short, wide and relatively fixed in position. It forms

Fig. 4.—A bolus of barium sulfate passing rapidly through the proximal jejunum. Note the widened loop with the obliterated mucosal pattern. Proximal to the bolus, the mucous membrane folds all points in the direction of motion.

an incomplete loop around the head of the pancreas and may be divided into a superior, a descending, a transverse and an ascending portion. The cap and superior duodenum are usually retentive, but in the remaining

portions of the duodenum peristaltic rushes and to and fro motion may be seen. In the duodenum the stream is of the intermittent type. Beyond the suspensory ligament of Treitz the speed of forward motion decreases. The barium stream tends to be continuous with an occasional peristaltic rush. Through the jejunum and ileum the progress of the meal is mostly a gradual creeping forward of the contents, becoming slower as it approaches the cecum. This progress is so slow that it is practically impossible to study the barium stream continuously because of the danger of overexposure to the patient. In some instances a complete arrest of the meal may occur in the ileum. If the patient is then allowed to eat, the contents will proceed into the colon without further delay.

The mucosal pattern of the small intestine shows many variations which seem to be specific for a given

Fig. 5.—The "snow flake" pattern, indicating retention of particles of barium in the mucous membrane folds after the main portion of the barium meal has passed.

set of physical conditions. Such a pattern is derived from the primary circular folds of Kerkring and from the secondary induced folds which may occur in the mucous membrane. The primary folds of Kerkring are largest in the duodenum and jejunum, become smaller and less frequent in the lower jejunum and ileum and may be poorly developed or absent in the terminal ileum. They are not obliterated by distention and they persist in postmortem specimens. Such folds project into the lumen of the small intestine in a circular or spiral form. Adjacent folds may be of different heights and point in different directions. According to Forsell³ the mucous membrane folds adapt themselves to the muscular contractions of the intestinal wall and also to the consistency and form of the meal. During roentgenographic examinations one is studying a working pattern; therefore the pattern of a given segment

3. Forsell, G.: Role of Autonomous Movements of the Gastrointestinal Mucous Membrane in Digestion, *Am. J. Roentgenol.* 42:143, 165 (Feb.) 1939.

depends on its anatomic character and also on its physiologic activity at the time of the examination. In the duodenum the pattern is coarsely reticular but may sometimes resemble stacked coins (fig. 3). While the stomach and duodenum are emptying, the jejunum shows a reticular or herring bone pattern when thinly coated by barium (fig. 2). During the passage of large boluses, the pattern may be obliterated except for circular folds near the periphery (fig. 4). As the meal progresses distally a "snow flake" pattern occurs owing to retention of small quantities of barium in the vasa digestiva (fig. 5). The central lumen is variable. When small amounts of barium coat the mucous membrane, the folds can be seen to meet near the center of the intestine. When larger quantities of barium are present, one cannot be certain of the presence of a central canal because of the obliteration of the pattern. If a small

Failure of rotation may result in finding the small intestine in the right half of the abdomen and the colon to the left side of the midline. This condition, also called mesenterium commune, is easily recognized by roentgen examination.

Fig. 7.—Mucous membrane pattern in the ileum. This appearance has been called the "stacked coin" pattern.

Fig. 6.—Longitudinal folds in the jejunum occurring as a result of segmental contraction.

quantity of gas is present, the central lumen may be more readily observed. Longitudinal folds of mucosa, the "barring" pattern of Forssell, may occur as a result of segmental contraction in the jejunum (fig. 6). Occasionally, one also sees a localized fuzzy appearance which I have attributed to a rapid movement at the time of examination.

In the proximal ileum the pattern is somewhat similar to that in the distal jejunum. Farther along in the ileum the pattern gradually changes. Frequently a continuous or segmented column of barium without a visible profile pattern is present. In other instances the pattern may resemble a stack of coins (fig. 7). Sometimes one observes a sharp change in density of the barium in the ileum as a result of increased secretion or dilution of the meal. Near the terminal ileum, longitudinal folds can sometimes be identified.

The frequency with which normal variations and congenital anomalies of the small intestine occur depends largely on the thoroughness of the examination and the examiner's ability to detect them.

Fig. 8.—Multiple large diverticula of the small intestine. Note that they are all placed along the mesenteric border.

Intra-abdominal hernia can be diagnosed by roentgen study of the small intestine. In this condition the coils are grouped closely and they may occupy the right, left or midabdominal position. In the patients studied by

Alexander⁴ the distal duodenum and duodenojejunal junction were located in an abnormal position.

Enterogenous cysts and aberrant pancreatic tissue are rare anomalies which may produce anatomic deformity of the duodenum. When small, these deformities are

Fig. 9.—Congenital veil producing distortion of the second portion of the duodenum. This patient also had gallstones, but there were no adhesions between the gallbladder and the duodenum. The arrow points to the duodenal deformity.

seen as an obliteration of the normal mucosal pattern, with or without a central filling defect simulating a polyp.

Congenital diverticula of the small intestine occur most frequently in the duodenum. Usually placed along the inner curvature, they vary in size from a few millimeters to several inches in diameter (fig. 8).

Congenital membranes and veils attached to the duodenum may produce roentgenologic appearances

Fig. 10.—Congenital anomaly of the jejunum resulting in a narrow segment. Note the dilatation and retention of the barium proximal to the lesion. Arrows point to the area of involved intestine.

which in some instances cannot be differentiated from pericholecystic adhesions or duodenal ulcers (fig. 9).

In 1906 Ochsner⁵ called attention to a more or less marked thickening of the intestinal wall from 2 to 4 cm. below the entrance of the common duct. Microscopic

sections taken from various portions of the intestinal wall demonstrated that this thickness was due to an increase in the number of circular muscle fibers present. The arrangement was somewhat like that seen at the pylorus, although the fibers were spread out in a more diffuse fashion. Ochsner was of the opinion that inflammatory processes in the duodenum or biliary tract might result in delayed passage of the contents because of spasm of these muscular fibers. I have not been able to corroborate his anatomic observations by roentgen examination of healthy persons.

Congenital defects which result in a narrowed small intestinal lumen or complete atresia are most commonly found in children. In most of the cases, these defects are incompatible with life. The routine use of study of the small intestine has enabled me to diagnose in one instance a narrowed jejunum in a white man. Operation on him revealed that approximately 5 inches of the jejunum was reduced to half its normal outside circumference. The lumen of this portion of the intestine was about the size of a lead pencil (fig. 10).

Fig. 11.—Lane's kink of the terminal ileum. The point of fixation of the ileum is indicated by arrow a; b is the tip of the appendix.

Meckel's diverticulum may sometimes be found during roentgen examination of the small intestine. In some instances this anomaly has produced a serious impairment of function as well as a definite anatomic deformity of the small intestine. I have seen a Meckel's diverticulum as large as one's thumb which was completely missed by roentgen study and two abdominal operations. In another instance the diverticulum was so large that it was mistaken for a segment of the small intestine. Whenever delayed motility occurs in the ileum, one should examine the intestine carefully for this anomaly.

Ileal stasis, a term seldom used in recent years, may result from a Lane's kink. One may suspect this condition if a partial obstruction is associated with a kinked and somewhat fixed terminal ileum. The anatomic deformity is thought to be due to adhesions which bind the mesentery of the lower ileum to the iliac fossa⁶.

(fig. 11). Clinically, some of these patients have been suspected of having duodenal ulcer, but their symptoms have been relieved by releasing the fixation of the terminal ileum.

The value of a roentgen study of the small intestine is increased by the use of a standard type of meal and technic of examination. With such a basis a specific roentgen appearance may be established for normal subjects. Such studies may well result in a clearer conception of the roentgen anatomy in disease states.

ROENTGENOLOGIC MANIFESTATIONS OF NON-NEOPLASTIC LESIONS OF THE SMALL INTESTINE

HARRY M. WEBER, M.D.

ROCHESTER, MINN.

My purpose in this paper is to discuss the roentgenologic manifestations of the more commonly encountered non-neoplastic diseases of the small intestine. There is not a great variety of such processes. Peptic ulcer of the duodenum and of the jejunum occurring after gastro-enterostomy is omitted, because these parts are so intimately associated with the stomach that they are more properly considered in connection with lesions of that organ. Acute inflammatory processes of the small intestine are not included because patients afflicted with them rarely are, and probably never should be, submitted to roentgenologic examination. Syphilitic and actinomycotic lesions of the small intestine have been reported in the literature, but such lesions are so exceedingly rare that for practical purposes they may well be omitted from a discussion of this kind. The literature also contains reports of cases in which animal parasites, notably *Ascaris lumbricoides*, have been demonstrated in the small intestine at roentgenologic examination; such instances are also comparatively rare, and the condition is mentioned here only by way of recognizing it. The non-neoplastic lesions of the small intestine more commonly encountered may be listed as follows, and this discussion will be confined to these:

1. Chronic enteritis.
Tuberculous enteritis.
Nontuberculous enteritis.
2. Diverticula.
Meckel's diverticulum.
3. Deficiency states.
4. Co-involvement of the small intestine by extrinsic non-neoplastic lesions.

THE ROENTGENOLOGIC EXAMINATION OF THE SMALL INTESTINE

I shall not attempt to describe the conduct of the roentgenologic examination of the small intestine in detail. However, the roentgenologic appearance of even the normal small intestine may vary widely, depending on the technic employed in the examination; therefore it seems proper to describe at least those features of the examination considered to be important.

The patient presents himself for examination in the morning after an overnight period of fasting. The first step is the roentgenoscopic survey of the abdominal field. If there is no evidence of intestinal obstruction the examination may proceed. The patient is asked to

drink 8 ounces (240 cc.) of a suspension made of equal parts by volume of barium sulfate and water. The roentgenoscopic examination of the stomach and duodenum is made in the usual way. Then the examiner attempts to express as much as possible of the opaque suspension from the stomach into the duodenum and jejunum. This is the first of a series of attempts the examiner makes to prevent a wide dispersion of the opaque material through long reaches of the small intestine. Ideally the suspension will be confined to the smallest possible number of intestinal loops and will be carried down the intestinal tract as a coherent compact mass. Usually only a certain quantity can be expressed from the stomach at a single roentgenoscopic session lasting from five to ten minutes, but enough will have left the stomach to permit satisfactory examination of the entire duodenum and upper coils of jejunum. The patient is then permitted to rest for a brief interval. To accelerate the spontaneous discharge of the rest of the opaque suspension from the stomach the patient is instructed to lie relaxed on his right side, for it seems that the stomach empties itself best in this posture. After from ten to fifteen minutes a lower series of intestinal coils are filled with the opaque suspension and the patient is again submitted to roentgenoscopic examination. Periods of rest followed by roentgenoscopic observations are repeated at intervals of fifteen minutes until the stomach has delivered all but an insignificant quantity of the suspension of the opaque medium into the intestine. At about this time a lull in the more vigorous intestinal movements sets in, and unless the intestine is stimulated to activity again the opaque material tends to become widely dispersed without distending the coils in the desired way referred to. A simple palatable breakfast, preferably chosen by the patient according to his taste and custom, is a pleasant and practical way to stimulate the intestinal motility at this phase of the examination. Immediately after breakfast, periodic roentgenoscopic examinations are resumed until such time as the opaque material has made its way to the lowermost portion of the ileum and cecum. The time required for the contrast material to pass from the stomach to the cecum varies considerably in apparently normal persons. Forty-five minutes of elapsed time is not considered to be abnormally fast; four or five hours, not abnormally slow.

Roentgenographic examinations, with or without the use of the Potter-Bucky diaphragm, are made at the examiner's discretion, to clarify doubtful or suggestive areas of abnormality and to supply a permanent record of the roentgenologic manifestations. It is worthy of emphasis, however, that the roentgenoscopic examination is the cardinal roentgenologic maneuver, and, in my opinion, no number of roentgenograms could satisfactorily supplant it.

To me the most satisfactory way of examining the lowermost portion of the ileum is by filling it in retrograde direction through the ileocecal orifice at the conclusion of the examination of the colon, by using a contrast enema. Examination is made before and after the patient is permitted to empty the opaque fluid from the colon. Under these circumstances the ileal coils are elevated out of the bony pelvis, are filled with fresh, undehydrated contrast fluid, and are well visualized and readily manipulated. Retrograde filling of the lowermost portion of the ileum can be effected in most cases if the examiner will make a special effort to do so. It is well to consider the roentgenologic examination of the lowermost portion of the ileum as part of the

examination of the colon in much the same way as the examination of the duodenum is considered to be part of the examination of the stomach.

CHRONIC ENTERITIS

Pathologically, chronic enteritis, using this term in its broadest possible sense, would include chronic intestinal lesions of tuberculosis, syphilis, bacillary dysentery and lymphopathia venereum as well as lesions caused by pathogenic fungi and parasites, and lesions for which a specific etiologic agent has not as yet been determined. It is probable that these lesions, whatever their cause may be, will have very similar gross pathologic features and they will be distinguished from one another only by their microscopic characteristics. Syphilitic, mycotic, parasitic and proved specific bacillary and streptococcal forms of enteritis occur so rarely as to be negligible in a practical consideration. Tuberculous enteritis and a nonspecific form of chronic enteritis of undetermined origin are the most common types of chronic enteritis encountered in practice.

In the truly voluminous literature that has accumulated on these two forms of chronic enteritis the clinical, pathologic, roentgenologic and therapeutic phases have been studied and described so often and so well that further elaboration seems not only unnecessary but presumptuous. I wish only to emphasize that the two diseases have many clinical, morphologic and roentgenologic features in common and to submit some suggestions for making at least a presumptive roentgenologic distinction between them.

Traditionally, intestinal tuberculosis is described as being either ulcerative or hyperplastic in character. Practically, a purely ulcerative or purely hyperplastic tuberculous intestinal lesion is but rarely encountered. Usually a combination of ulceration and hyperplasia is observed, and one or the other feature is found to be predominant in the picture. A true hyperplastic tuberculous lesion of the small intestine is notoriously uncommon.

Fig. 1.—Left, colon distended with contrast enema; right, after evacuation of contrast enema and redistention with air. Tuberculous ileocolitis. The patient had cavernous tuberculosis of the right lung.

mon. Masson and McIndoe¹ reported the one case in which a lesion of this type was observed at the Mayo Clinic and, significantly, the lesion was discovered in a part of the small intestine caught in a right paraduodenal hernia. Traditionally, too, tuberculosis of the intestine is considered to be a combined enterocolic

disease, that is, tuberculous lesions are observed to be distributed throughout the colon and in the small intestine as well, and especially in the ileocecal region. This distribution of tuberculous lesions is but the rule to which there are many exceptions. Proliferation, necrosis, cicatrization, ulceration and perforation, with development of extra-enteral abscesses and fistulas, are

Fig. 2.—Left and right, phases in the examination of the small intestine. Tuberculous ileitis. At necropsy no other focus of tuberculosis was found.

universally recognized features in the pathogenesis of tuberculous intestinal lesions.

In 1932 Crohn, Ginzburg and Oppenheimer² reported a series of cases of benign, subacute or chronic, necrotizing and cicatrizing inflammation of the small intestine. Neither these observers nor any of the many who have conducted investigations on the cause of the disease since that time have given a satisfactory answer as to its cause. The pathologic features of the disease have been described in detail, and the similarity of the gross pathologic characteristics of this disease to those of intestinal tuberculosis is striking in all descriptions. As in tuberculous enteritis, the pathologic process is subacute or chronic; proliferation, necrosis, ulceration, cicatrization, perforation and the formation of perienteral and extra-enteral abscesses and fistulas are characteristic features. Macroscopically, it is always difficult, and usually impossible, to distinguish the nontuberculous from the tuberculous form, and cases have been reported, that of Schapiro³ being a noteworthy example, in which the ultimate correct diagnosis was in doubt even after expert and thorough microscopic examination. If distinction between the two diseases is difficult, even when the diseased tissue is made available for macroscopic examination, it is hardly surprising that a roentgenologic differentiation should also be difficult, as indeed it is. The following observations have been found to be of value, at least in cases in which the original pathologic process has not been too badly obscured by very extensive ulceration and development of abscesses and fistulas.

Like the colon, the small intestine is a tubular organ, and since pathologic processes deform the one in much the same way as they do the other, the same roentgenologic criteria of diagnosis can be applied to the small intestine as are applied to the large intestine. There are several forms of chronic colitis and, as I have pointed out elsewhere,⁴ all of them deform the

colon in the same fundamental ways. The roentgenologic distinction between the different etiologic types of chronic colitis is made chiefly on the distribution of the pathologic process in the colon, but roentgenologic evidence of disease in other organs and the results of other clinical tests must frequently be drawn on to reach the final diagnosis. Besides these, the experienced observer can frequently recognize what, for want of a better term, I have called a certain "look" by which, intuitively almost, he perceives the underlying cause for the changes he sees. The roentgenologic manifestations of the different forms of chronic colitis are much more familiar than those of similar processes in the small intestine because of their very much greater incidence, but the same roentgenologic diagnostic criteria are applied to lesions of both parts of the intestine.

As has been mentioned, the tuberculous and nontuberculous forms of chronic enteritis have so much in common morphologically that the two are not readily distinguished from each other even at gross pathologic examination and, therefore, not at roentgenologic examination. But, as in the colon, close comparison of the roentgenologic appearances often shows a different roentgenologic "look" of the two diseases.⁵ This is largely related to the contours the affected segment assumes when filled with the contrast material. The contours of the tuberculous intestine have typically a rougher, more corrugated, appearance corresponding to a more irregular, disconnected insemination of the ulcerohyperplastic process (figs. 1 and 2). In its roentgenologic manifestations the nontuberculous form of chronic enteritis imitates the classic, familiar picture of chronic ulcerative colitis very closely. The contours are characteristically smooth and the narrowing is uniform, corresponding to the typical diffuse, even development of the underlying pathologic process (figs. 3 and 4).

Other aids in the differentiation are chiefly those concerned with the exclusion of tuberculosis. Investigation of extra-enteral foci of tuberculosis, especially in the

Fig. 3.—Left, colon after evacuation of the contrast enema; right, after redistention with air. Nontuberculous ileocolitis. Microscopic examination of the resected specimen failed to show evidence of tuberculosis.

lungs, should always be made when evidence of chronic enteritis is at hand. If a focus of active pulmonary tuberculosis is found to be coexisting with any non-neoplastic lesion of the small intestine below the duodenum, the intestinal lesion should be considered tuberculous until proved otherwise. Conversely, in the

absence of such a focus the intestinal lesion is likely to be nontuberculous. Isolated intestinal tuberculosis occurs just often enough, however, that this conclusion is not to be drawn definitively. Instances in which nontuberculous enteritis is associated with pulmonary tuberculosis of questionable activity have also been observed.

Fig. 4.—Left, ileum and upper part of colon filled with opaque suspension administered by mouth; right, after evacuation of opaque enema. Nontuberculous ileitis. At necropsy, no evidence of tuberculosis was found either in the intestine or elsewhere in the body.

Other diagnostic clues may be offered by the discovery of calcified mesenteric lymph nodes, the application of intradermal tuberculin tests and the search for *Mycobacterium tuberculosis* in the stools. It is granted, of course, that a definitive diagnosis will certainly not be reached in many instances, and the roentgenologic examiner will often find it necessary to confine his diagnosis to a description of the general morphologic character of the process and its distribution in the intestinal tract. His clinical and surgical colleagues will be able to carry on if this is done with a reasonable degree of accuracy.

DEFICIENCY STATES

Peculiar changes in the roentgenologic appearance of the small intestine are often observed in certain states of dietary deficiency, especially when steatorrhea, with or without diarrhea, is one of the principal clinical features. These roentgenologic changes have been seen in such conditions as nontropical sprue, pellagra, celiac disease in children, pancreatic insufficiency, chronic alcoholism and some other conditions of long continued primary or secondary nutritional deficiency. At present I am not prepared to state that the roentgenologic appearance of the small intestine is identical in all of the different types of deficiency disease enumerated. But this much can be said: Whenever these changes are encountered in the roentgenologic examination of the small intestine, they have many features in common, and a distinction between the various types of deficiency disease on the basis of roentgenologic appearances alone is not as yet attempted.

Pillai and Murthi,⁶ Snell, Camp and Watkins,⁷ Mackie and Pound,⁸ Golden⁹ and others have described the roentgenologic changes seen in these conditions. One of the surprising features is the marked depression

of motility throughout the intestinal tract, and this is the more striking if the patient has been complaining of diarrhea. Peristaltic activity is definitely subdued, the contrast suspension making its difficult, slow way down the tract much as if it were being poured through a half-lifeless tube. Peculiar segmentation of the intestinal loops is commonly found. Contracted segments are observed to alternate irregularly with dilated ones. In another phase, a loop that was dilated is found to be contracted. The contours of well distended segments may be abnormally smooth at one period of roentgenoscopic observation, abnormally shaggy at another. The internal relief of involved loops may be markedly suppressed or markedly exaggerated. Fantastic agglomerations of the opaque suspension take place. In the normal small intestine the opaque suspension assumes a smooth homogeneous continuity; here part of it is collected in a pool in an isolated dilated segment, another part is clumped in an apparently unrelated amorphous mass, and the rest of it assumes the appearance of a flocculent precipitate throughout a long stretch of some other part of the small intestine. The changes are the more marked the more well defined is the clinical pic-

Starr and Gardner¹⁰ noted atrophy, dilatation and passive congestion of the entire intestinal tract; Whipple¹¹ described extensive deposits of neutral fat and fatty acids in the intestinal mucosa, with passive congestion and cloudy swelling of the viscera; in one of three cases reported by Blumgart¹² ileal ulceration, distention of the cecum and atrophy of its mucosa were noted. That

the intestinal secretions are grossly abnormal is evident from physical and chemical examination of the stools and intestinal secretions.

On the basis of my own observations I am inclined to discredit the importance of inflammatory changes, such as edema, ulceration and infiltration of the intestine, in the production of this roentgenologic syndrome. It seems to me that the roentgenologic changes are more plausibly explained by holding the degenerative changes accountable for the abnormal motility and for some of the bizarre intestinal patterns observed, while the abnormal secretions are made responsible for the other peculiar roentgenologic manifestations.

DIVERTICULA OF THE SMALL INTESTINE

Duodenum.—Diverticula are found in the duodenum more frequently than in any other part of the intestine except the sigmoid colon. The most common site of origin is near the ampulla of Vater. They may be single or multiple, very small or very large, but even when large they are usually symptomless. In rare instances they become large enough to produce symptoms of partial or intermittent obstruction mechanically, and in this event radical therapeutic measures may be necessary for relief. It is conceivable too that ulceration may result from prolonged retention of ingested matter, and symptoms may develop from such a situation. The diagnosis is strictly roentgenologic when made before operation or necropsy. Even when small, the characteristic extraluminal outpouching is readily recognized as the contrast meal is observed as it passes along the course of the duodenum after it has passed through the pylorus. Sometimes diverticula are distended with gas or with fluid or with both.

Jejunum.—The diverticula found in the jejunum are larger, as a rule, than those in the duodenum, and they are more frequently multiple than single. In the

Fig. 5.—a, phases in the examination of the small intestine; left, the earlier phase shows no roentgenographic evidence of the diverticulum, although it was identified at roentgenoscopic examination; right, the arrow points to the diverticulum; b, left, the abdomen fifteen hours after administration of 2 ounces (60 cc.) of castor oil and twenty-four hours after patient took the contrast meal (a); the arrow points to the residue of the contrast suspension in the diverticulum; right, after evacuation of contrast enema.

ture, and the involved segments have a decided tendency to return to normal as the patient gives evidence of clinical improvement.

At the present time one can do little more than speculate about the morphologic and physiologic significance of these roentgenologic changes. In only a few cases were actual morphologic studies made available.

jejunum, as in the duodenum, the diverticula are usually symptomless, although instances have been reported in which the diverticula were held responsible for symptoms such as borborygmi and intermittent cramps after the ingestion of food. The diagnosis of jejunal diverticula is likewise a roentgenologic problem. Since the outpouchings are usually large, they are recognized with comparative ease as the contrast meal makes its way through the jejunal coils. Frequently the diverticula fail to evacuate the contrast substance rapidly, and they are recognizable even after the jejunal lumen in the immediate vicinity has contracted and all but the smallest residue of the opaque substance has been expelled from the mucosal folds.

Ileum.—Diverticula are but rarely found in the ileum, and those not designated as Meckel's diverticula rarely are associated with clinical symptoms. The roentgenologic appearance of ileal diverticula is the same as that of diverticula in the duodenum and jejunum.

MECKEL'S DIVERTICULUM

This developmental anomaly occurs in about 2 per cent of the population, males predominating in a ratio of 2:1. It is always found somewhere in the first 5 feet (150 cm.) of ileum above the ileocecal valve. Almost any variation in size, shape and position may be encountered. Thus Dixon and Famiglietti¹³ and Goldstein and Cragg¹⁴ described a gigantic Meckel's diverticulum, 66 cm. in length, which was found in a girl aged 5 years. Often the diverticulum is simply a small, budlike projection from the ileal lumen.

Fig. 7.—Meckel's diverticulum and hyperplastic ileitis. The arrows point to the diverticulum; left, in the roentgenogram made after evacuation of the contrast enema; right, in the specimen removed by resection.

Pemberton and Stalker,¹⁵ reviewing twenty consecutive cases in which Meckel's diverticulum was encountered at operation, classified the cases into three groups: (1) those in which there were no symptoms, (2) those

in which there were symptoms of intestinal obstruction and (3) those in which there were symptoms of intestinal bleeding. Only eight of the twenty patients had symptoms believed to be due to the diverticulum; in the remaining twelve cases the diverticulum was discovered at the time laparotomy was performed for some other abdominal lesion.

Fig. 8.—Meckel's diverticulum; left, lower part of the ileum filled with contrast suspension administered by mouth; right, diagrammatic representation of the condition found at operation: A, Meckel's diverticulum; B, neck of diverticulum; C, narrowed ileum.

The clinical diagnosis of Meckel's diverticulum, even when the diverticulum is diseased, is notoriously difficult. However, the condition can frequently be suspected and a presumptive diagnosis made on the basis of exclusion of other possibilities. The roentgenologic examination assists in the diagnosis of Meckel's diverticulum in two ways: (1) by the actual demonstration of the diverticulum somewhere in the lowermost 150 cm. of the ileum; (2) failing this, by assisting in the exclusion of other intestinal lesions as causes of symptoms.

Very few successful attempts at demonstrating Meckel's diverticulum by roentgenologic methods have been recorded. Case¹⁶ was the first to demonstrate this anomaly, and many years elapsed before another instance was recorded in the roentgenologic literature. Then others, among them Pfahler,¹⁷ Allemann¹⁸ and Prévôt¹⁹ reported cases. Up to the present time Meckel's diverticula have been demonstrated roentgenologically on but six occasions at the Mayo Clinic. Since these diverticula vary so widely in their gross morphologic characteristics, a typical roentgenologic appearance is not to be described. The roentgenologic appearance may, however, be expected to reflect the morphologic contour of the particular diverticulum. A review of the cases seen at the Mayo Clinic and those reported in the literature shows that Meckel's diverticulum will usually be found in those coils of the lower part of the ileum that are situated near and somewhat to the right of the midline and at or near the level of the umbilicus. One of the six cases seen at the clinic was reported by Skinner and Walters,²⁰ and the preoperative roentgenologic diagnosis of Meckel's diverticulum (fig. 5 a and b) was confirmed at operation. In three cases in which the diagnosis was made, the

patients were not submitted to operation and hence the diagnosis has not been confirmed (fig. 6). One patient had extensive hyperplastic ileitis, which was recognized roentgenologically. The diverticulum was discovered in the resected portion of the intestine and a review of the roentgenograms after operation revealed the site of the diverticulum and its contours accurately (fig. 7). In the fifth case a preoperative diagnosis of perforating obstructing neoplasm of the ileum was made (fig. 8). At the primary operation the real nature of the lesion was not determined with certainty, but it seemed to be a narrow, annular tumor of the ileum associated with marked inflammation. Ileocolostomy was performed. At the second operation, which was performed twenty-five days later, it was found the inflammatory process had subsided, and the real nature of the lesion became apparent. It was a Meckel's diverticulum 3.5 cm. in diameter at its base and 7.5 cm. long; the anterior portion had become ulcerated. There was also considerable inflammation of the ileum on each side of the diverticulum. A review of the roentgenograms in the light of these surgical observations revealed that the true morphology was readily apparent but misinterpreted preoperatively.

As roentgenologic experience with the diagnosis of Meckel's diverticula accumulates, it seems reasonable to expect that the condition will be recognized more frequently at roentgenologic examination. Such Meckel's diverticula, however, as are small and communicate with the ileal lumen by a very wide neck will be recognized only with the greatest difficulty, and many of them will inevitably escape roentgenologic detection. Careful and painstaking examination of that part of the ileum in which this anomaly occurs will, I think, result in many more accurate diagnoses of this condition than have been recorded in the past.

EXTRINSIC PROCESSES

The small intestine seems to be co-involved by pathologic processes extrinsic to it with relatively greater frequency than is the large intestine. Usually such processes are neoplasms which deform the small intestine segmentally either by direct extension and invasion or by producing trophic ulceration which extends into the lumen. Neoplasms of the pancreas seem especially prone to do this, but tumors of the mesentery and of the female pelvic organs may act similarly. Of the extra-enteral non-neoplastic processes which extend to and involve the small intestine, perforating diverticulitis of the sigmoid colon and salpingo-oophoritis seem to be encountered most frequently. The roentgenologic evidence of the extrinsic nature of the process is obtainable at the roentgenoscopic examination, if at all; palpation will possibly reveal the extrinsic mass or a more diffuse tenderness or muscular rigidity than would be expected if the disease were confined to the intestine. If actual perforation into the intestinal lumen has not taken place, considerable deformity of the affected segment may be observed, yet as the mucosal surface is carefully examined it will be noted that the mucosal pattern, although altered considerably by functional changes and by edema and submucous infiltration, will be left unbroken throughout the deformed segment. Conditions of this kind, however, may be very confusing and will often demand fullest cooperation of all special diagnostic services if the correct diagnosis is to be made preoperatively. Fortunately, situations of this kind are not commonly encountered.

CLINICAL ASPECTS OF CHRONIC DISORDERS OF THE SMALL INTESTINE

EVERETT D. KIEFER, M.D.

BOSTON

This study has been restricted to the role of the small intestine in the etiology of chronic abdominal disorders and to the considerations that must be given it in the diagnosis of chronic digestive complaints.

Clinical signs and symptoms of disorders of the small intestine arise as a result of interference with the physiologic functions of digestion, absorption and motility.

SYMPTOMATOLOGY OF DISEASE OF SMALL INTESTINE

There are few symptoms which are highly diagnostic of disease of the small intestine. Obstructive lesions may cause vague prodromal symptoms such as a sense

Fig. 1 (case 1).—Appearance of the abdomen during an acute attack of intermittent intestinal obstruction caused by postoperative adhesions. Barium series during symptom-free intervals were negative. The large gas bubble in the left upper quadrant is in a dilated loop of jejunum.

of fulness or cramplike pain after meals, but the almost completely fluid nature of the content of the small intestine makes for an "all or none" type of obstruction. There is no obstruction until suddenly there is complete obstruction with an acute onset of symptoms that are either persistent or intermittent, depending on the mechanical status of the point involved.

Hypermotility of the small intestine produces symptoms that are less dramatic and more subtle in character. Abdominal distress immediately after meals, flatulence and diarrhea are suggestive of hypermotility. Grossly inadequate absorption results in large, foul, fatty stools, failing nutrition, calcium imbalance and avitaminosis.

Anemia is not uncommon in disorders of the small intestine and is the result of inadequate absorption of

From the Department of Gastro-Enterology, the Lahey Clinic. Read before the joint meeting of the Section on Gastro-Enterology and Proctology and the Section on Radiology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 19, 1939.

iron or other blood forming substance or more commonly the result of chronic blood loss. Gross hemorrhage also occurs and the passage of a large amount of red blood by rectum points to a possible lesion in the jejunum or ileum.

Fig. 2 (case 2).—Partial obstruction and marked dilatation of the jejunum caused by adhesions and a malfunctioning gastro-enterostomy from torsion of the jejunal loop, five hours after the ingestion of barium sulfate.

PHYSICAL SIGNS

The general physical signs of disease of the small intestine are malnutrition, anemia and signs of vitamin deficiency. Inspection of the abdomen may disclose an

Fig. 3 (case 2).—A, appearance of patient Jan. 14, 1938, showing the malnutrition and the mental apathy which were present. Weight, 104 pounds (47 Kg.). B, appearance May 19 showing the striking change in his appearance after surgical relief of the obstruction and the associated improvement in his nutrition. Weight, 144 pounds (65 Kg.).

irregular pattern of dilated small intestine with or without visible peristalsis. If the abdominal wall is thin, it is usually possible to distinguish distended loops of small intestine from the stomach or the colon by the characteristic pattern and the type of peristaltic activity.

The other important abdominal finding may be a mass. Benign and malignant neoplasms of the jejunum or ileum vary in size, feel rounded and are usually movable and somewhat tender. An intussuscepted mass is firm but soft and gives the impression of being elongated or sausage shaped. Infectious granulomas may also be elongated but are harder and more ropelike.

ROENTGENOLOGIC SIGNS

By far the most important single laboratory procedure is the x-ray examination of the gastrointestinal tract, yet a remarkably large percentage of lesions of the small intestine are missed in the ordinary routine study. Although the study of motility of the small intestine, outline and mucosal pattern with serial films is well known and the interpretation well appreciated by specialists in roentgenology, these methods are not generally applied in gastrointestinal diagnosis, and the small intestine remains the relative blind spot in x-ray

Fig. 4 (case 3).—Rigid annular constriction with a sharp line of demarcation between rigid bowel wall and distended intestine, three hours after the ingestion of barium sulfate. Diagnosis, annular carcinoma of the jejunum.

diagnosis of the digestive tract. There follows the axiom that lesions of the small intestine are not found unless they are looked for.

There are practical objections, especially the cost of films, to the routine employment of numerous serial films in every case, and a compromise may be effected in the form of a film taken between two and three hours after the barium meal. Since, in the average case, the head of the meal reaches the cecum at this time, a considerable portion of the jejunum and ileum is well outlined and the film has much more diagnostic value than the ordinary six hour film. The examiner should be familiar with the clinical history and alert for symptoms pointing to the small intestine so that additional films can be ordered in suspicious cases. The rather wide variations in the normal mucosal patterns and outlines of the small intestine introduce difficulties in interpretation, but long experience in viewing normal patterns sensitizes the examiner to the occasional abnormal appearing loop.

Intubation of the small intestine combined with x-ray studies with air and opaque mediums recently described by Miller, Abbott and Johnston¹ promises to add further diagnostic aid.

Fig. 5 (case 5).—Stasis and dilatation of the ileum and a rounded filling defect within the lumen of the ileum produced by intussusception, three hours after a barium sulfate meal.

CHRONIC OBSTRUCTION DUE TO ADHESIONS

One of the commonest forms of chronic organic disorders of the small intestine is the intermittent obstruction caused by postoperative adhesions.

In case 1 there was a history of a panhysterectomy and appendectomy performed fourteen years before

Fig. 6 (case 6).—Abnormal x-ray appearance of the jejunum characterized by exaggerated markings and sharply serrated borders. The ileum is smooth and dilated with spastic areas. Diagnosis, chronic nonulcerative enteritis.

admission. About nine years later the patient began to have attacks of severe, cramplike pain in the lower part of the abdomen, occurring at intervals of from one

to twelve weeks, lasting several hours and sometimes accompanied by vomiting. Between attacks she had no important gastrointestinal symptoms. Characteristic of this condition, not only her physical examination but the gastrointestinal x-ray films were entirely negative during these intervals. Fortunately, while the patient was under observation she experienced a typical attack, which made it possible to make an x-ray examination of the abdomen during an attack (a diagnostic opportunity which should never be overlooked) (fig. 1). This disclosed a dilated, gas-filled loop of small intestine indicating obstruction, which was confirmed at laparotomy.

In association with chronic partial obstruction there is not only a disturbance of motility but sometimes a marked disorder of nutrition due to fear of eating

Fig. 7.—The normal small intestine may show considerable variation in position, caliber, outline and mucosal pattern. This film shows one of the common variations in the outline and mucosal pattern of the small intestine.

because of the resulting pain, frequent vomiting and diarrhea. Mild states of malnutrition and vitamin deficiency are common, and occasionally an extreme avitaminosis develops comparable to severe pellagra.

In case 2 a gastro-enterostomy had been performed for pyloric obstruction thirty-five years before admission. Until five years before the patient came to the clinic he had been well, but at that time he began to reduce his food intake gradually because of the abdominal pain that followed meals of ordinary size. His chief complaints on admission were neuritis in both legs and diarrhea. The physical manifestations were those of severe pellagra including emaciation, anemia, edema, polyneuritis, glossitis, dermatitis, proctitis and mental changes. Parenteral fluids and energetic vitamin therapy improved his condition, but an increase in the quantity of food resulted in obstructive vomiting. X-ray studies (fig. 2) showed obstruction of the proximal jejunal loop at the gastro-enterostomy, which proved to be due to adhesions and torsion of the loop. Surgical relief

1. Abbott, W. O., and Johnston, C. G.: Intubation Studies of the Human Small Intestine: A Nonsurgical Method of Treating, Localizing and Diagnosing the Nature of Obstructive Lesions, *Surg., Gynec. & Obst.* 66: 691-697 (April) 1938.

resulted in the patient's return to health. Figure 3 reveals the striking improvement in the patient's appearance. The nutritional disturbances had become so marked that in the clinical picture they overshadowed the gastrointestinal disorder responsible for the condition.

TUMORS OF THE SMALL INTESTINE

Benign and malignant tumors of the small intestine may cause obstruction which is progressive but may be steady or intermittent. An annular carcinoma of the small intestine characteristically tends to give rise to slowly progressive obstruction with increasing pain and vomiting. The loss of weight in this type of case is usually marked and rapid. The stools contain occult blood and there is anemia as a rule. Figure 4 demonstrates a typical annular, constricting filling defect of a carcinoma in the jejunum with dilatation and stasis above it. Surgical resection in this case was followed by recovery, and the patient is alive seven years after the operation.

New growths of the small intestine which are not annular in structure but are mural or polypoid in type are the most frequent cause of intussusception in the adult and are prone to cause intermittent attacks of obstruction similar to the attacks associated with post-operative adhesions. The attacks tend to become progressively more frequent and more severe. As in the cases of chronic adhesions, the x-ray examination may be disappointing except when carried out either during or immediately after an acute attack.

Fig. 8 (case 7).—Distortion of the outline and mucosal pattern of the duodenum beginning in the second portion with extension of the process into the jejunum producing changes in the outline and mucosa. The process extends well down into the jejunum, but the lower part of the jejunum is almost normal in the mucosal pattern, indicating that the inflammation was limited to the duodenum and upper part of the jejunum. Diagnosis, ulcerative enteritis.

DIVERTICULA OF THE SMALL INTESTINE

Meckel's diverticulum is another important cause of intussusception in young adults. The mechanism is probably identical, since in most cases there is in relation to the diverticulum either an inflammatory mass or a small benign tumor.

Occasionally it is possible to demonstrate an intussusception of the ileum by x-ray examination, as illustrated

by the following case: A man aged 34 had intermittent spells of cramplike, midabdominal pain for over a year. Films of the small intestine showed not only disturbed motility but the presence of gas and barium, which outlined the filling defect caused by the tumor of intussuscepted bowel (fig. 5).

Fig. 9 (case 8).—Changes in the outline and pattern of the mucosa of the upper part of the jejunum one hour after the ingestion of barium sulfate. The lower part of the jejunum and the upper part of the ileum show contraction and rigidity over an extensive area. Dilatation and saccululation of the lower part of the ileum are present. Diagnosis, chronic ulcerative and cicatricial enteritis.

Also in cases of bleeding from the lower portion of the intestine, particularly in children and young adults, Meckel's diverticulum should be considered, since the occurrence of aberrant gastric mucosa within the sac giving rise to peptic ulceration, hemorrhage and perforation is a well known clinical entity.

CHRONIC INFLAMMATORY DISEASE

Our knowledge of chronic inflammatory disease of the small intestine other than tuberculosis dates mainly from the report of Crohn² in 1932.

SUBACUTE OR CHRONIC NONULCERATIVE ENTERITIS

A subacute or chronic nonulcerative inflammation of the small intestine is frequently seen and is illustrated by a school boy aged 15 who had complained of malaise, anorexia, mild abdominal distress, mild diarrhea, a slight elevation of temperature and moderate leukocytosis for three months. The colon was normal by x-ray and by sigmoidoscopic examination, but definite changes in the mucosal pattern of the small intestine were demonstrated (fig. 6). There was no blood in the stools. Following treatment the symptoms disappeared and subsequent x-ray films showed a return to normal of the pattern of the small intestine.

CHRONIC ULCERATIVE ENTERITIS

The following case of chronic ulcerative enteritis is an example of a more severe and more chronic form of active inflammatory disease of the small intestine showing evidence of ulceration of the mucosa but with-

2. Crohn, B. B.; Ginzburg, Leon, and Oppenheimer, G. D.: Regional Ileitis. *J. A. M. A.* 99: 1323-1329 (Oct. 15) 1932.

out extensive hyperplastic reaction: A married woman aged 31 had complained of chronic abdominal pain for eighteen months. On examination she was found to have fever, a moderately severe anemia, mild leukocytosis and occult blood in the stools. Gastrointestinal

Fig. 10 (case 9).—Changes in the mucosal pattern of the jejunum and markedly irregular coils of ileum with numerous crater-like depressions in the outline one hour after the ingestion of barium sulfate. Diagnosis, chronic regional ulcerative and cicatricial ileitis.

x-ray examinations showed changes in the mucosal pattern, irregularities in outline and in caliber and some loss of flexibility in certain areas of the upper portion of the small intestine. The rest of the tract was normal (fig. 8).

HYPERPLASTIC STAGE

The hyperplastic stage is more chronic and may show surprisingly extensive involvement of the small bowel. The case illustrated in figure 9 shows x-ray changes throughout the small intestine which are highly reminiscent of the changes found in the colon in extensive ulcerative colitis.

From a roentgenologic point of view, chronic ulcerative enteritis of either the small or the large bowel produces obliteration of normal outlines, loss of flexibility, shortening of loops, stenosis and contraction of the lumen and occasional fistula formation.

TUBERCULOUS ENTERITIS

Tuberculous enterocolitis produces changes in the ileum and proximal colon which, from a roentgenologic standpoint, are indistinguishable from nonspecific enteritis. Brown and Sampson³ pointed out that localized hyperirritability of the intestine was indicative of early ulcerative lesions in the mucosa. As the process advances, changes in the mucosal pattern, irregularities of outline and lumen and finally rigidity and narrowing are demonstrable by x-ray examination. Since it is generally accepted that ileocecal tuberculosis practically never occurs except secondarily to active, open pulmonary disease, the differential diagnosis is not a common problem.

3. Brown, Lawrason, and Sampson, H. L.: *Intestinal Tuberculosis*, Philadelphia, Lea & Febiger, 1926.

INTESTINAL CHANGES IN DEFICIENCY STATES

While malnutrition and deficiency states are common results of organic disease of the small intestine, it is also true that avitaminosis may lead to secondary changes in the intestinal tract which are sufficiently definite to be demonstrated by x-ray study. Irregular distortions of the normal mucosal pattern, localized dilatation of the lumen and a tendency for the barium sulfate to form pockets in isolated loops are noted. These changes are thought to be produced by edema of the mucosa, disturbances in the motor activity and loss of tone in the intestinal muscle.

Figure 12 shows an example of small intestinal atony found in a young woman with chronic malnutrition.

FUNCTIONAL DISORDERS OF SMALL INTESTINE

Purely functional disorders of the small intestine are difficult to establish on a sound clinical and laboratory basis. Nevertheless, experience with functional indigestion leads to the belief that in some cases disturbances of the small intestine play a prominent role. This disorder is usually manifested by signs and symptoms of hypermotility.

In some cases of hypermotility of the small intestine the barium sulfate meal may reach the cecum in less than one hour, and the entire meal may pass into the colon in three or four hours. A sense of extreme fullness in the upper part of the abdomen immediately after a meal is rather characteristic of distress of the small intestine. An unusual amount of borborygmi and a sensation of motion and gnawing within the upper part of the abdomen noticed immediately after a meal is also

Fig. 11.—Contracted irregular lumen with loss of flexibility and sinus formation. Diagnosis, tuberculous granuloma of ileocecal region.

indicative of hypermotility. Rapid emptying of the small intestine may cause diarrhea and excessive flatulence.

Factors that are important in causing functional disorders of the small intestine are an irritating type of diet, habitual catharsis, alcohol, food idiosyncrasies or allergic phenomena, endocrine disorders, general fatigue and nervous or emotional factors. The excessive use of

cathartics is commonly associated clinically with disorders of the large bowel, but it is also true that cathartics have a pronounced effect on the small intestine. Patients with true food idiosyncrasies usually have a pronounced effect within a few minutes after ingesting the specific foods, and their symptoms often indicate a marked irritation of the small intestine.

SUMMARY

Chronic intermittent obstruction, most commonly caused by adhesions, is characterized by acute attacks of abdominal pain interspersed with asymptomatic

Fig. 12 (case 9).—Rapid filling of the small intestine and the dilated atonic appearance present throughout the jejunum and ileum one and a half hours after the ingestion of barium sulfate. Diagnosis, atony of intestine; malnutrition.

periods with negative physical and x-ray manifestations. Positive diagnosis is often made possible by roentgenograms taken during an attack.

In some cases nutritional disturbances may be the outstanding feature.

Annular tumors produce gradually increasing obstruction.

Mural and polypoid tumors cause intermittent attacks of intussusception which increase in severity and frequency.

Except for Meckel's diverticulum, diverticula are usually asymptomatic.

Tuberculous enteritis usually secondary to pulmonary tuberculosis rarely involves the ileum alone.

Chronic nonspecific enteritis may occur as a febrile condition with irritation of the small bowel, as an ulcerative enteritis with fever and anemia or as a granulomatous condition with thickening, obstruction and fistulas.

Functional disturbances are manifested by signs and symptoms of hypermotility.

X-ray diagnosis depends on signs of disturbed motility and changes in the outline, caliber, flexibility and mucosal patterns as illustrated by films taken at suitable intervals after a barium sulfate meal.

605 Commonwealth Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. CHAMBERLIN, WEBER AND KIEFER

DR. SARA M. JORDAN, Boston: The first striking thing which comes to attention is the need for more complete x-ray examination of the small intestine. We probably cannot, in all cases, do what Dr. Chamberlin and Dr. Weber so adequately outlined, but we can follow their example and use the fluoroscope at frequent intervals and take frequent films and use either their technic or a standard technic in each laboratory, so that we have something on which to base our judgment of the condition of the small bowel, and this especially in those cases in which there is any reasonable suspicion of disease in the small intestine. We can also adopt what Dr. Kiefer has shown to be a satisfactory routine method of making some estimate of the motility of the small intestine, by a film taken in two or three hours, in addition to one taken after the jejunum and ileum have been almost completely emptied. That simple addition to the routine procedure will help us in the acquisition of more knowledge of the small intestine. We do not have endoscopy for the small intestine, but we shall use, I am sure, the Osler-Abbott intubation. Peritoneoscopy, which Dr. Benedict has described, will also help in visualizing parts of the exterior of the small intestine. We are constantly going to have more and more help, but we shall still depend mostly on increased facilities and increased skill in the visualization of the small intestine through roentgenology. The second point which has been important in this group of papers is that we need constantly more and more security in our diagnosis of functional disease of the digestive tract. In the past when we have eliminated disease of the stomach, biliary tract and colon and have found no gross obstruction in the small intestine, we have said that the patient who complains of abdominal symptoms is probably neurotic. It is an age-old difficulty of internal medicine to separate the sheep from the goats, the neurotic from those with real organic disease. This new knowledge that we are finding of the small intestine will help do that. We shall be able to determine in addition to the functional disease of the colon and of the stomach, of which we have talked so much, definite indications of functional disease of the small intestine and probably in more cases we shall be able to find real organic disease. I should like to stress the fact which was emphasized by Dr. Weber, namely that repeated examinations are important.

DR. ROSS GOLDEN, New York: For years we complacently did our examinations of the stomach, the duodenum and the colon and didn't bother to look at the loops of small intestine which happened to be filled at the time of examination. At Presbyterian Hospital in New York we began to do a special examination of the small intestine ten years ago. The clinicians soon became convinced of its value and it has become a standard, frequently requested procedure. Our technic differs from that of Dr. Weber in that we use a smaller quantity of barium sulfate; namely, 2 ounces (60 Gm.) with the necessary water to enable a patient to take it. The smaller quantity is advisable because there is less danger of one loop obscuring another and, furthermore, we withhold food for at least five hours unless the barium reaches the cecum in a shorter time. There are three important indications for a special, small intestine which might be mentioned: (1) diarrhea, (2) bleeding and (3) persistent abdominal pain remaining unexplained after adequate examinations of the stomach and duodenum or of the large intestine have been done. This deficiency state is of unusual interest. The manifestations on the x-ray examinations are not specific. There are a number of different conditions which may produce those changes. Vitamin deficiency is probably the most important. The Abbott tube has been used at Presbyterian Hospital in from sixty to seventy cases. As a result the mortality in intestinal obstruction has been reduced to 7 per cent. We believe that the development of this tube is of major importance. Not only does it change the surgical operation from an emergency to an elective procedure but also it enables diagnoses to be made which would be extremely difficult any other way. I have never seen the

giving of barium sulfate produce any deleterious effects in the presence of disease of the small intestine. I should like to second what Dr. Kiefer said about the importance of examining the small intestine during an attack. Not infrequently I request the clinician to let us do the examination during an attack. I should like, furthermore, to emphasize Dr. Weber's remarks about the use of spot films with or without compression, particularly with compression. We have been able to show things in that way which would be very difficult to demonstrate by other methods, particularly in the terminal ileum. One interesting fact which came out in a study of the autopsy protocols of primary malignant disease of the intestine in our department of pathology was the frequency with which metastases in other parts of the gastrointestinal tract occur with carcinoma of the small intestine.

DR. W. EDWARD CHAMBERLAIN, Philadelphia: I too have found it necessary to examine the patient during the attack in order not to miss the diagnosis. In one case it took a third laparotomy to discover the lesion, which would have been missed the third time had it not been for the fact that the patient entered an attack while on the way to the operating room. There is one observation which I feel I should record here under the heading of motility changes of the intestinal tract. There is a type of human being who is subject to exaggerated constipation without abdominal distention and with relatively few symptoms until catharsis is indulged in. The bowel movements are markedly inspissated. That type of individual has invariably exhibited a strange hypermotility of the upper intestinal tract; in fact, in a number of cases repeatedly examined I have found that the head of the barium column is in the descending colon in approximately one hour from the time it passes the mouth. That is a definite hypermotility of the stomach, the small intestine and the colon, yet it occurs in individuals who will go perhaps seven or eight days, after the one hour of hypermotility, before they will discharge some of that barium from the rectum. I want to emphasize what Dr. Golden has said about the tremendous value of the Miller-Abbott tube in intestinal obstruction. We too have found our patients made comfortable. We are able to feed them and give them water and prepare them for operation in a perfectly spectacular way. We owe a great debt to those who created the Miller-Abbott tube and taught us how to examine the small intestine with x-rays.

DR. T. L. ALTHAUSEN, San Francisco: There are two points I should like to make in connection with the subject presented here this afternoon. One is to mention a method to prevent the excessive spread of barium through the small intestine during fluoroscopic examination, which is in use by the radiologists of the University of California Hospital and has not been mentioned today. It consists of passing a tube into the duodenum and injecting the desired amount of barium mixture through the tube. With this method the usual successive passages of barium through the pylorus are absent, resulting in more satisfactory examination of the small intestine. Even marked hypermotility of the intestine does not necessarily impair intestinal absorption. We unexpectedly found this in studying intestinal absorption by a test the description of which will appear shortly in the *American Journal of Digestive Diseases*. With this test, four of five patients in whom the head of the barium column at the six hour examination of a gastrointestinal series was seen at the splenic flexure of the colon or distal to it proved to have normal intestinal absorption.

DR. JOHN T. MURPHY, Toledo, Ohio: A number of the authors and discussers have used the term "spot" film and, as the men at this meeting are not all radiologists, I feel that it would be well to inject a word of caution about this procedure. When "spot" films are made at the fluoroscope, it is necessary to "step" up the current so that the film may get an adequate exposure in a short time. This produces a marked increase in both the direct and the secondary radiation. Repeated too frequently, this exposure may cause harmful effects on the personnel in the fluoroscopic room.

DR. GEORGE W. CHAMBERLIN, Philadelphia: In the cases in which I have used a water barium meal I have found normal motility to be an hour and a half to three hours from the

stomach to the cecum, and the small intestine is completely empty in from five to seven hours. There are some patients who show variations in the normal motility. In some instances in which the motility is unusually rapid, we have considered the possibility of allergy. Dr. Jordan mentioned the functional disturbances of the small intestine. This is the field that I have been particularly interested in and one of the reasons why I have urged every one to recognize a normal appearance of the roentgen pattern in the small intestine. There is evidence that such conditions as hypothyroidism and hyperthyroidism, adenomas of the pituitary, disturbances in the chemistry of the blood and other conditions outside the abdomen may produce an abnormal roentgen appearance of the small intestine. I should like to disillusion those of you who are gastroenterologists concerning what Dr. Kiefer said about the cost of the examination, particularly about the cost of the film. In our department we feel that the film is the least expensive part of the roentgen examination. In other words, adequate fluoroscopic and radiographic examination of the small intestine is possible if the radiologist will take the time to do a complete examination.

DR. HARRY M. WEBER, Rochester, Minn.: Meeting as we are with the Section on Gastro-Enterology and Proctology with whom our professional associations are very intimate, I think that they should have the assurance of the members of the Section on Radiology that we are continuing to lend our best efforts to what Dr. Jordan has aptly called "separating the sheep from the goats." In other words, we consider it our first duty to separate that group of patients who have organic disease as the basis of their symptoms from a much larger group whose symptoms are to be explained in another way. It has been said that in the past this has not been done very efficiently in cases of disease of the small intestine. Discussions of this type, together with more diligent application of roentgenologic methods to the small intestine, will do much to make the management of diseases of this division of the alimentary tract more satisfactory. Dr. Chamberlin emphasized that it means a lot of hard work—hard work, of course, for the roentgenologic examiner, which means first of all more diligent and more frequent use of the roentgenoscopic method in this field. None of us today consider the examination of the stomach or the colon adequately done without roentgenoscopic examination. Why then should the small intestine, the most difficult of all divisions of the alimentary tract to examine roentgenologically, be exempted from this the most useful and illuminating of all roentgenologic maneuvers?

DR. DAVID ADLERSBERG, New York: We all welcome the fact that we are beginning to think in terms of the small intestine. In regard to the interesting work of Dr. Kiefer, it is also my feeling that many of the complaints after gastroenterostomy and resection are due to disturbances in the small intestine. Some of these cases resemble mild cases of pellagra and sprue. As to the remarks of Dr. Chamberlin, I am also interested in cases in which there are hypermotility of the small intestine and colonic hypomotility, and have felt that in some of these cases the latter may be considered a compensatory mechanism for the former.

Inherited Structural Defects.—Most apparent of the human "abnormalities," by their very nature, are those which affect external appearance or sensory functions. At circus sideshows you can see some of the more startling examples of "black" gene caprice—midgets, dwarfs with misshapen heads and bodies, Negro albinos, "India-rubber" men, etc. But for each one of these there are dozens of other surface or structural defects found in the everyday walks of life. In fact, it may be said that most persons have some inherited structural abnormality—if we include, as "abnormal," conditions that are unusual, but not necessarily harmful or defective. Going further, and taking into consideration "hidden" recessive genes which singly produce no effect, it is pretty certain that every one of us is carrying some one or another of these genes.—Scheinfeld, Amram: You and Heredity, New York, Frederick A. Stokes Company, 1939.

THE RESPONSIBILITY OF THE MEDICAL PROFESSION IN THE MOVEMENT FOR 'BIRTH CONTROL'

GEORGE W. KOSMAK, M.D.

NEW YORK

The avoidance of conception as a result of normal sexual intercourse has been made in recent years the subject of extensive scientific study as well as of propaganda movements directed largely by lay and, in part, by professional groups. The desirability of birth control in a limited medical sense has been extended into the realms of sociology, economics and eugenics, and as a result a considerable confusion of thought and purpose has been developed. The doctor, however, has been made to feel that his participation in the world-wide discussion is a minor one; he is accused of failing to keep in step with modern requirements and to be unwilling to support a movement of such paramount importance. Undoubtedly the medical profession has been hesitant to take an active part in a propaganda with which many of its members are out of sympathy, largely because of the hysteria and exaggeration which have accompanied its dissemination. However, it must be evident that the profession cannot refuse to recognize the firm conviction on the part of the public that procreation can, and perhaps should, be regulated.

As physicians, we should constitute an active and influential force by which this effort can be guided in the proper direction. How shall this be accomplished? Is it for the medical profession to propose means and methods or shall it all be left to chance? It should be possible to view the problem from its various angles and to formulate certain standards of thought and practice through which at least a partial solution of a difficult question may be reached. In other words, and speaking broadly, there is a sane as well as what may be termed an insane approach to a question which is agitating a great many people. Moreover it becomes necessary to define as nearly as we can the responsibility of the medical profession and what its part must be in the application of knowledge thus far available. This may not prove a simple task, but it is one which cannot well be evaded or shirked. Mere blind opposition will accomplish nothing and will only react to its detriment. It is essential therefore that in our discussion we consider the problem from its varying aspects: historical, social, economic, legal and medical. Full consideration of all these is necessary to a proper understanding of this complex situation. For the control of conception is not a simple matter if we reflect on its wider implications, some of which are already becoming evident, among them the effect on our population balance. It is essential therefore that not only the medical profession but the public at large be thoroughly informed on the subject and that reason take the place of hysteria and unreason.

EARLY EFFORTS

Man has attempted to control his procreative powers probably since the dawn of history, and the actual limitation of the family by direct means was sought as soon as civilization as such became manifest. It is interesting to read of the crude methods employed by primitive races and the survival of some of these up to the present by people supposedly of a higher degree of

intelligence. A knowledge of the physiology of impregnation was and still is an unknown quantity to most, but it is of interest to note in many instances that the methods for avoiding it were fairly ingenious and successful and, if not, there was always at hand a resort to abortion or infanticide. Strangely enough, with all these efforts to avoid conception there went almost hand in hand a desire to relieve infertility in women by procedures quite as thoughtful as the reverse. The responsibility for undesired pregnancy was not invariably placed on the woman's shoulders, and we find that mutilating operations were practiced on men for the same purpose by various primitive people who were evidently aware of the function of the seminal fluid.

As civilization advanced, crude methods and mechanical devices became gradually displaced by more rational procedures but, from a careful reading of the history of contraception, it is evident that the desire for prevention is not a new thing; it is merely the search for and distribution of effective and harmless means of achieving this which characterizes the later day movement. However, during the nineteenth century we find a noteworthy departure. From a purely personal basis, contraception in the larger sense became involved with social and economic problems. Woman's emancipation, so called, has served to stimulate her self expression. She demands what she terms protection against undesired or too frequent child bearing, and this attitude has extended to all social levels; the underprivileged classes are no longer to be discriminated against.

BIRTH CONTROL IN ENGLAND

Himes¹ accords to Francis Place, an Englishman who lived from 1771 to 1854, the same position in social education on contraception that Malthus holds in the history of overpopulation theories. Malthus had approached the problem of birth control from an entirely different standpoint, for he believed that unchecked population growth in a country would in time overreach its available food supply. He recommended moral restraint and essentially condemned birth control as we know it today. Moral restraint did not imply restriction in intercourse within the married relationship but rather postponement of marriage until the contracting parties were able to support possible offspring. It is readily seen why the more radical ideas of Place and his successors developed a larger following. Place made a strenuous campaign in England in 1822 and the subsequent years, circulating handbills freely among the working classes, describing the use of a vaginal sponge or coitus interruptus as effectual contraceptive methods. Place and his followers, although including medical conditions, made a strong plea for their devices as factors in preventing poverty and raising the standard of living of the masses. Place also argued that birth control would favor earlier marriages and that postponement led to vice and prostitution. Place was not a physician and he was not supported by the medical profession but he frequently sought the advice of its members. He did introduce the organizational element into the control of contraception, which has developed into the prominent propaganda movement that we know today.

After the clamor for social reform died down in England, following the general readjustment after the Napoleonic period, interest in birth control likewise diminished but found a new field of activity in America, where the publication of several books by Richard Owen

Read before the Section on Obstetrics and Gynecology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

1. Himes, N. E.: *Medical History of Contraception*, Baltimore, Williams and Wilkins Company, 1936.

and Dr. Charles Knowlton, among others, served to revive the agitation. The latter recommended chiefly astringent douches after coitus, and his book "The Fruits of Philosophy" was widely sold in this country and in England.

During the last quarter of the nineteenth century, prosecution of several writers and publishers in England characterized the campaign for democratization of birth control knowledge by publicity. The Free Thought Movement of that period, under the dominance of Annie Besant, Bradlaugh and others, became involved in court procedures and in 1878, as the result of two jury trials, a sentence combining prison and fines was imposed on a Mr. Truelove, a book publisher of London. The public of England became intensely stirred, but the results of various appeals were unsuccessful, although the trials did aid finally in making legal the general free distribution of contraceptive knowledge. There seems to be little doubt, moreover, that the diffusion of birth control knowledge has reduced the English birth rate by half since 1876.

Mrs. Annie Besant brought out in 1884 a booklet entitled "Law of Population," which found general favor as shown by the fact that more than 175,000 copies were sold, the last edition appearing in 1897. Additional contraceptive devices, including the soluble suppository and the rubber cervical cap, were proposed. Another pamphlet, written however by a doctor, also appeared during this time and by 1927 its circulation had passed the half million mark. Its author, H. A. Allbutt, a Leeds physician and fellow of the Royal College of Physicians of Edinburgh, was accused in 1887 before the General Medical Council of having published an indecent book and his name was ordered taken from the Medical Register, mainly, it seems, because the author's conduct was considered unprofessional in permitting advertisements of contraceptives to be included. Appeals were unsuccessful as far as Allbutt was concerned, but his pamphlet continued to circulate widely.

Various individuals and organizations too numerous to mention have identified themselves with the birth control movement in England. Characteristic of more recent sentiment is the stress laid on birth control as a health and eugenics measure rather than as one solely dictated by economic status.

PROPAGANDA IN THE UNITED STATES

The birth control movement in the United States during the nineteenth century was associated rather closely with that in England. A number of physicians wrote similar books of advice and direction for married couples, but there developed likewise a good deal of quackery and also an association of the movement with certain erratic individuals who were active in a variety of religious and quasireligious cults and organizations. Liberal political thought, as expressed by socialists, communists and even anarchists, included birth control propaganda, and legal restrictions against the distribution of information and devices were incorporated in the laws dealing with obscenity and indecency in the federal Postal Code and in various state laws. An interesting social experiment of this time was the Oneida community of New York State, which existed for a period of years during the latter part of the nineteenth century. This was a voluntary communistic colony which was founded and led by John Humphrey Noyes and combined its peculiar religious doctrines of Perfectionism with a complex system of marriage in which control of conception was exercised by a peculiar type

of coitus, a sort of male continence. This colony constituted an interesting eugenic experiment but, its essential principle being unphysiologic and contrary to what Himes terms "the sexual pattern of the male developed over a long physiological period," it did not long survive. Moreover, internal dissensions and the force of public opinion assisted the disintegration.

Others took up the birth control propaganda in this country and many books had wide circulation notwithstanding the many prosecutions brought about through the Comstock laws. These legal restrictions centered in certain postal regulations and curbed for a considerable period the dissemination of birth control information and devices. Of course all sorts of evasions were practiced, but in the course of time legitimate medical indications became more clearly recognized. Teachers of prominence in medical schools talked about and approved of contraceptive measures yet for many years did little to advance the scientific side of the subject. In the early part of this century the name and personality of Margaret Sanger became prominent through her dramatic efforts in circulating literature and opening clinics for contraceptive advice. She came into conflict with the law, and her persecution by the police served merely to draw greater attention to her self-assumed martyrdom. Her attitude toward the subject may be regarded perhaps as exaggerated and often hysterical, but her influence was undoubted and she succeeded by her strength of will and determination in interesting and enlisting many well meaning and wealthy women for the support of the American Birth Control League and allied organizations. Mrs. Sanger claimed that from the first she attempted to operate through the medical profession but the unwillingness of its members to assist her forced her to independent action.

COMMERCIAL EXPLOITATION

It has been claimed (Himes,² p. 326) that the failure of the medical profession to accept its responsibilities is the principal cause for the extensive commercial and antisocial participation in the contraceptive movement. There can be no question of the enormous and highly profitable traffic in preventives—good and bad—sold widely everywhere at the present time without apparent restraint. One must carefully divorce the legitimate from the illegitimate demands in arriving at a conclusion about what should be done to restrain sales and secure standardization of products.

There is one aspect of the problem to which insufficient attention has been given by the profession, namely its responsibility in the teaching and practice of birth control measures when these are indicated. The history of the movement shows however that, particularly in recent years, physicians have given thought to the matter of judging the efficacy of various methods of contraception and have instituted scientific studies to evaluate them. Medical indications have also been more closely defined. But it must be acknowledged that the stimulus has come largely from lay groups whose sense of direction and application has not, as a rule, been satisfactorily guided. For much of this the doctor, both in an individual and in a collective capacity, must assume the blame. It should not have been necessary to establish extramural clinics for this purpose; whatever advice and treatment were necessary could have been done in the established hospital clinic and doctors' offices. Moreover, the assumed illegality of contraceptive advice has, in my belief, had an unfortunate psychologic effect, and the confusion that exists in the minds of physicians likewise requires clarification.

It is questionable whether the imposition of statutes, either state or federal, can control a movement of this kind, in which concerted agitation, largely by interested lay groups, has too often distorted and magnified indications. Medical men have given their names in aid of efforts to do away with restrictive laws, so that a physician's right to prescribe as he saw fit would not be invaded. There can be no question about the paradoxical and absurd situation created by the retention of outmoded statutes, both federal and state, which have interfered with legitimate practice and contributed little to control the indiscriminate dissemination of contraceptive advice and products. The commercial exploitation that has resulted can be regarded only as disgraceful. In a recent magazine article the number of dollars involved is quoted in millions. An extensive and thriving business has been developed by a large number of manufacturers and distributors whose field of activity is by no means directed to those people legitimately entitled to employ their devices. The resultant advertising campaign has become nauseating and under the more acceptable and supposedly refined appellation of "feminine hygiene" an important and serious matter has become flouted for purposes of financial gain. We can thank the unrestrained popular propaganda for this, as we can for the lack of sexual restraint which has become so evident. There is a hope but, it must be admitted, a rather faint one, that through proper education and the possible help of the medical profession we may arrive at a more sane attitude toward this question.

THE COMMITTEE ON CONTRACEPTION

The American Medical Association long resisted efforts to give its official sanction to the study of contraception but finally, at a meeting of the House of Delegates held in Atlantic City in 1935, provided for a study committee, which has rendered two reports.² This action by organized medicine should be given careful consideration, and I want to review briefly the reports of the special committee which thoroughly discussed and studied the various claims that have been made concerning the need for contraceptive practices, as well as the accepted medical indications and the possible dangers associated with the widely disseminated propaganda. The committee approached the subject from various points of view, beginning with that dealing with overpopulation. This problem is very complicated and resolves itself today into a question of selected growth rather than a haphazard increase. If this means a wider acceptance of the need of contraceptive practice applied in particular to the unfit, using this term in a wide sense, the committee was hesitant to enter into an endorsement of such a movement because it felt that, as far as the United States or similar countries is concerned, we have as yet little to guide us in formulating a national policy on the subject. The committee also believed that it must limit its consideration of the question as it refers to the relationship of physician and patient. The committee called attention to the inadequacy or ineffectiveness of many contraceptive procedures and to the actual dangers of others. While clarification of laws is needed, there was no evidence that existing laws interfered with a physician who felt called on to give information to patients. The committee expressed its opposition to independent and unlicensed birth control clinics and suggested the need of instruction to medical students in the entire subject of fertility.

2. Report on the Use of Roentgen Rays for Contraception, Council's Committee on Contraception, J. A. M. A. 111:1767 (Nov. 5) 1938.

As for eugenic considerations, the committee concluded that there is little scientific basis to justify wider birth limitation except in the case of acknowledged transmissible congenital diseases. Moreover, there seems to be no evidence that a wider dissemination of contraceptive information would establish a better social and economic equilibrium in society. While family limitation among lower income groups might prove advantageous, the lack of adequate and effective methods makes this difficult, especially where the exercise of ordinary restraint is inapplicable.

Medical considerations naturally could be more appropriately discussed by a group of physicians and more definite conclusions could be presented. The committee recognized that voluntary limitation of conception may be necessary to safeguard the health of some women, as in the presence of active tuberculosis, nephritis, heart disease, certain psychopathic conditions, arteriosclerosis, chorea, pernicious anemia, a recent serious illness or operation and a number of other conditions, especially in women physically incapable.

A recommendation that a responsible group be authorized to develop standards for judging contraceptive materials was not endorsed until the year following the introduction of the first report, when it was referred to the appropriate councils of the Association. It was also reaffirmed that contraceptive information should be limited to physicians in their private practice and to regularly licensed clinics under medical supervision. This formal recognition of the subject by organized medicine constitutes an important step, but thus far no impression can be recorded on the status of the question as a whole. It will take years to curb and regulate a movement which has had such wide and appealing publicity.

RESULTS

I have attempted to review briefly the history of the birth control movement and its development in this country. While efforts to develop contraceptive practices are by no means new, the effects on our social structure have become more evident during recent decades, particularly the influence on birth rates and population balance. This influence cannot be disregarded, for we must face the fact that the birth rate of this country is diminishing and that the older age groups soon may dominate the younger. The former are outside of the productive and reproductive periods and it will take more time to determine the effect of such biologic interference on the economic and social status of a nation.

Much has been said about the influence of contraceptive practices and their free discussion on morals and a changing attitude toward parenthood and child bearing. This is a broad subject and its interest to the profession may be secondary, for undoubtedly the physician no longer occupies the position of adviser and family counselor which he did in the past. Nevertheless I feel that he has an important role to play, for it would have been well if he had chosen or had been chosen to carry out the practical application of a contraceptive program in a sane and reasonable manner. Organized medicine, speaking through its official body, has attempted to define this position but with what success remains to be seen. However, the individual physician may feel that he must be guided by conscience or religious precepts and it would be unwise in such instances to resort to persuasion in any effort to bring about a change of views. A considerable portion of the active practitioners of medicine acknowledge

and believe that contraception is justified and plays a part in their professional duties. It would appear reasonable, therefore, to review the practical phases of contraceptive therapeutics, if I may so designate them. Before doing so it may be well to discuss briefly the religious aspects of the question.

THE "SAFE PERIOD"

Many religious bodies have condemned severally interference by artificial means with the process of insemination, particularly the Catholic church, and yet we find apparently a change of sentiment in recent years, since fairly definite knowledge is available about the so-called safe period. While one must approach the subject with caution, it is evident that no condemnation by church authorities attaches to the practice of this method of contraception by married people. Prominent Catholic clergymen and physicians have endorsed and written about the availability of the "safe period." This view assumes, of course, that the time of ovulation can be determined absolutely in all cases. Unprejudiced medical opinion is somewhat less certain. While ovulation in most cases occurs during the middle of the intermenstrual month, a variety of physical and emotional factors may advance or postpone menstruation and thus throw calculations out of balance. This uncertainty is of particular moment in cases in which pregnancy is contraindicated for definite medical reasons.

The so-called Ogino-Knaus theory has stimulated a vast amount of clinical and biologic investigation. Undoubtedly there are women in whom a "safe period" exists, but in actual practice the procedure demands a degree of restraint and cooperation which cannot be relied on to do what is so glibly claimed for it. How can such a method of self control be imposed on that large group of people who most need a foolproof method of either child spacing or contraception? Mathematical calculations based on menstrual dates are scarcely reliable or opportune in moments of sexual excitement. It places too much of a strain on human nature.

THE DOCTOR'S QUANDARY

The doctor, assailed by conflicting opinions, naturally is in a quandary when consulted by patients in the legitimate practice of his profession. He is well aware of the consequences of pregnancy when this is contraindicated medically or in certain instances socially. Whatever his principles, he may find it necessary to sacrifice these to expediency. He may in consequence be damned if he does and equally damned if he does not. There must be a middle ground on which the physician may stand which is legitimate and yet not contrary to the just demands of his patients. Therefore, what advice and suggestion can we accept as practitioners for the practical application of contraceptive knowledge now available?

Numerous technical manuals on contraception have been published for the use of physicians which offer a multitude of methods. It is well in each instance to study the individual patient and adopt the most suitable procedure to the case. Passing by what may be termed physiologic methods such as continence and coitus interruptus (withdrawal), the commonly employed methods may be divided into chemical and mechanical.

METHODS IN USE

The principal chemical methods include the medicated douche and a variety of jellies, suppositories and foam powders. The douche is effective mechanically to a certain degree and may be rendered spermicidal by the addition of soap suds, a variety of astringents

(vinegar, alum and the like) or chemicals (mercury bichloride or saponated solution of cresol). The uncertainty of the former and the dangers of poisoning by the latter render this procedure undesirable in most instances. Jellies and pastes contain a variety of chemicals suspended in a water soluble vehicle to be injected by an appropriate device into the vaginal vault. Suppositories are solids melting at body heat, usually of gelatin or cocoa butter, incorporated with boric acid, chinisol, quinine or a similar drug. Foam tablets are stable in the absence of moisture and are made up of sodium bicarbonate and a solid acid such as tartaric or boric. They depend for their activity on producing a mechanical barrier at the cervical os, as well as on the spermicidal effect of the carbonic acid gas generated and the incorporated spermicide. A variety of powders for vaginal insufflation have also been employed.

These procedures depend largely for their effectiveness on the occlusion of the cervical opening, and the jelly is perhaps the most suitable. On the whole, however, they do not prove as highly effective as the actual occlusive pessary or the condom. Vaginal barriers can be made out of soft absorbent materials such as wool tampons or sponges, saturated perhaps with vinegar or some chemical solution or made from rubber in the form of a cervical cap or a diaphragm. The latter, supplemented with a jelly, is generally regarded as the most effective device and is widely used in contraceptive clinics, where it serves as the basis for the mystery which it is claimed is freely accessible to the rich and denied to the poor. The occlusive pessary must be carefully fitted to be effective, and the necessary manipulations may prove offensive to some women, but evidently most of them have overcome any possible scruples.

The foregoing methods are limited to the woman and applied before each exposure. Prolonged protection has been sought in the form of a variety of intra-uterine devices as well as subjecting the ovaries or testes to irradiation. The injection of sperm to produce spermatoxins has also been made the subject of extended experiments. Intra-uterine stems and rings are mentioned merely to be condemned. Their dangers are so evident that they should never be employed, notwithstanding the claims made for them. The field for irradiation of the ovaries to produce either temporary or permanent sterility is too limited for general discussion and we have too little satisfactory or definite knowledge about spermatoxin to warrant its consideration in general practice.

METHOD USED BY THE MALE

The condom is perhaps the better known and more common contraceptive device for use by the male, and an enormous expansion of its manufacture and distribution has taken place in recent years in this country. Of its use and safety there can be but little question. However, popular contraceptive propaganda has been directed largely to the woman, who is made the responsible partner. I wonder whether the various agitator groups would have been so successful in their appeals for sympathy if the responsibility for taking contraceptive measures had been lodged primarily in the male?

Complete sterilization of either man or woman by ligating the seminal tubes or the oviducts is somewhat out of the province of this discussion, but there is a growing sentiment that vasectomy in particular should not be limited to the mentally defective.

The relative value of the various methods thus briefly outlined is based on their efficacy and comparative harm-

lessness. It is in this field that authoritative and unprejudiced information is needed, and we may hope that an official body, preferably medical, may in time promulgate the desired knowledge. Extended studies have been made by the special birth control organizations and others, but little has been made available to physicians through official publications. The choice of method depends on the particular indication and the particular patient and also on whether contraception shall be temporary or permanent. Certain medical indications are distinct and perhaps permanent, certain social indications may verge closely on the medical and perhaps be only temporary. I have already referred to the group of transmissible diseases. Fortunately they are not numerous and in many instances the pathologic condition itself may constitute a barrier to pregnancy. When organic disease is present, including disorders of the heart, lungs, kidneys or blood forming organs, a physician need not hesitate; but there is another group of cases in which merely a state of overfertility may come into the question.

Fertility among individuals varies greatly and is dependent on a number of factors. Frequent child bearing, aside from its social and economic aspects, may have a decidedly depleting and perhaps harmful effect on a woman's general health and well-being. No one would deny the desirability of properly spaced pregnancies or even a reasonable number of children in order to avoid the drain on a woman's physical resources, which have had added to them so many other demands in more recent years. We cannot measure today a mother's ability to bear children by the standards of the past or by the much heralded occasional large families so dramatically shown on the screen or the Sunday supplements of our daily papers. The economic value of large families to factory workers and farmers is doubtful in this present day and age, and changing social and housing conditions call for a changed point of view. Unfortunately we have gone back a little too far in the popular estimate of the size of the family which, as far as the number of children is concerned, has gradually drifted to a point where a population balance is no longer being maintained. The physician, however, is often drawn into the picture, and his advice is sought by harassed parents who may not have found their way to a convenient birth control clinic where no embarrassing questions are asked. What shall he do? If truly acquainted with the facts, he should not hesitate to take the steps necessary for the welfare of that particular patient, provided he knows what to do and how to do it. Continence seems to be out of the question as a remedial agent in most cases; he cannot control nature's urge and he would get little encouragement or cooperation if he attempted to do so.

It is difficult to make a rule for the proper spacing of children, but an interim period of not less than two years should prove a desirable physiologic reply to this question. This brings up the consideration of the problem of postponing the first pregnancy in a young married couple. The universal dissemination of the birth control propaganda has fixed quite firmly in the minds of many people that such postponement until a convenient or suitable time is a perfectly legitimate and proper desire for a variety of good, or at least apparently good, reasons. What with our already late marriages, this has increased the average age at which the first labor takes place with a consequent increase in possible abnormalities, including a demonstrable higher incidence of toxemia and operative intervention with

its attendant morbidity and mortality. Undoubtedly a great many instances of sterility are covered up by the use of contraceptives which might have been discovered and treated at an earlier period. Moreover, the psychologic effect of avoiding pregnancy in the earlier years of married life is, in my belief, inherently unfortunate because it makes of this perfectly normal function an undesired complication, in many instances to be accepted finally if it cannot be avoided. It is true there may be extenuating circumstances in individual cases, but accepting contraception as a first stage in marriage is contrary to sense and to reason. It takes from possible parenthood that aspect of dignity and desirability which contributes much to connubial happiness.

MATERNAL MORTALITY

There is one further aspect to this problem to which I want to call attention. We have heard much in recent years about the high mortality associated with child bearing in the United States—that six women die out of every thousand who give birth to a living child. Ignorance, neglect and lack of proper and adequate care have been ascribed as causes, and constant efforts are being made by the medical profession and interested lay groups to reduce the preventable deaths, which are calculated as about one third or more of the total number. Is it possible that a knowledge of these facts has made women fearful of pregnancy and thus stimulated a demand for contraceptive measures? And in this connection we must likewise think of the many abortions with their high toll of death. If one half of the women who died from preventable causes and a like number of babies who were stillborn or who were lost as the result of abortions could have been saved, we might have less need to worry about our declining population. We are told that a wider resort to contraceptives would avoid these needless deaths of mothers and that legalized abortions, if contraceptives failed, are indicated in undesired pregnancies. It seems to me that this constitutes an illogical manner of thinking. We should be grateful for the fertile women and preserve their function, not inhibit or destroy it. Pregnancy must be made safer, it must not be regarded as either an unfortunate accident or a disease, and the increased resort to contraceptives is not the answer to the problems of maternity. The procreative instinct must not be stilled; our young women should be encouraged to develop and not to hamper it.

PHILOSOPHIC BASIS

The wider use of contraceptives is not apparently bringing about that unalloyed state of bliss which certain groups and individuals have promised. Doctors have been looked on as obstructionists to progress in this matter. But we are not obstructionists, we are merely doubters. There has been much sentimental appeal and much loose thinking on this subject and, notwithstanding all that has been said, we are still far from a satisfactory solution of the question of whether conception can be completely or satisfactorily controlled by artificial means. In the meantime the physician must play his part and assume his responsibilities. Whether he concludes to limit his participation to the strictly medical indications for contraceptive advice or whether he is ready to acknowledge the desirability of spacing children or limiting their number when this is needed, he should inform himself of the necessary procedures and their proper application and look on this knowledge as a part of his therapeutic armamentarium. If he declines to do so because of inherent principles or

religious beliefs, that is a matter for his own conscience and for which he should not be condemned.

I feel that too much attention has been centered on the mechanics of birth control and too little on the underlying philosophy which should govern its application. It would be preferable to have the physician consider the points of view of the eugenicist, the biologist, the economist and the student of population rather than the so frequently hysterical "contraceptive propagandist." It can hardly be expected that the practicing physician will familiarize himself sufficiently with all the varied factors in the problem, but he should be prepared to evaluate and carry out whatever procedures are necessary as an essential part of his practice. He is a participant in other fields which have a bearing on public health, why not in one of an import equal to that dealing with the prevention of communicable and other diseases? In the handling of a patient afflicted with tuberculosis, syphilis, diphtheria, pneumonia and other illness, he not only administers the remedy but in doing so he must observe the relation of this patient to the community. A similar point of view may be applied to contraceptive measures. There are definite indications for their employment in the presence of disease which have been satisfactorily formulated, but how and when and where to employ them is not at the present time a matter of general medical knowledge, and there is a prevalent hesitancy throughout the profession to make use of whatever knowledge we do possess. It would appear incumbent for medical schools to give such instruction, including not merely a demonstration of means and methods but to implant in the student's mind the wider implications of these practices which should be a part of a physician's armamentarium.

It is frequently claimed that economic and social conditions are the underlying reasons for family limitation. However, if this were true we would not find the procedure so widely practiced among those who may be designated as belonging to the middle and higher income groups. No, we must look elsewhere for such reasons and among the latter must be included the influence of what I myself regard as a vicious propaganda movement, developed and continued by false sentiment and inadequate reasoning. Physicians as a group have failed to evaluate this fact or to have exerted their influence in its regulation. This is a problem committed to their early attention, so that a solution may be possible with benefit to those most concerned, namely the parents of the future.

23 East Ninety-Third Street.

ABSTRACT OF DISCUSSION

DR. CHARLES E. GALLOWAY, Evanston, Ill.: I agree with Dr. Kosmak that the medical profession has an important responsibility in the matter of birth control. I should like to mention two important factors: the first is that women do not find their chief sexual expression in sexual intercourse but in reproduction, and the second that we should teach the public the truth; namely, that according to our present knowledge there is no satisfactory method of birth control. Many women and most men are being led to think that a woman's sexual life should imitate that of a man, and our psychologists seem to be the chief source of this erroneous notion. Every erotic book is filled with this same idea. Women discuss the matter freely these days and come to their physician with the query "Why is intercourse not the same with me as with my husband?" The answer is, I suppose, "Why does your husband not have half the babies?" The supreme act of any woman's existence is reproduction and she will be healthier and more normally adjusted to her surroundings if she does reproduce a reasonable number of times. The majority of the women who consult

physicians today do not have need for their advice and it would be to their advantage if they were so occupied with the responsibilities of a growing family that they would not have time to become so introspective. The second great responsibility of our profession is to disseminate the truth that we really do not have any satisfactory means of preventing pregnancy. Too many of our profession are conducting birth control clinics and in other ways going before the people, telling them that, if a certain procedure is followed or a certain gadget used, intercourse will not result in conception. There is no gadget or procedure that does not fail a good percentage of the time and there is no time in the month when conception cannot take place. In my private practice I see an average of one patient who is pregnant against her will about every two weeks. She invariably comes with the story that she went to a birth control clinic or a doctor and was fitted with a diaphragm and told that by using it properly she would not conceive. I have also delivered at least ten so-called "rhythm" babies. I have seen the published statements of some of my colleagues maintaining that hundreds of diaphragms had been fitted without a failure, and you know that such a statement is not the truth. Therefore, our two chief responsibilities are, first, the dissemination of knowledge relative to the proper place of reproduction as regards the happiness and well being of women and, second, that the present methods of birth control are far from satisfactory.

DR. JOSEPH L. BAER, Chicago: I am convinced that those who seek information about family limitation and family spacing for whatever reason are entitled to get that information from their physician. The Council's Committee on Contraceptives of the American Medical Association hopes that clinical research of adequate quality will enable it to make recommendations within the next year. The public interest is directly concerned with the endless stream of newborn who by known medical criteria are reasonably certain to become public burdens. The legislatures which have sanctioned sterilization are far sighted and are serving the public interest. I believe that the influence of the American Medical Association should be directed toward furthering this method of control of an unfit population. I am equally convinced that the present wave of deliberate family limitation, based on the desire of the parents to have only as many children as they can rear and educate as they would like them to be reared and educated, will give way in due course to the normal desire and most parents to have more children than this present handicap seems to permit. Finally there is great anxiety lest the widespread dissemination of contraceptive information will undermine the morals of our youth. License and promiscuity are far more current today than they were a generation ago. This is observable in all walks of life. This is a problem of the home. Ethical values and morality must be instilled in children by their parents. It is my hope that the current wave of lax morals will eventually subside as our home life regains its stability and its recognition of the essential value of all the virtues. I should like to call attention to what I think was a most significant movement in this whole field. Last fall the Student Religious Association of the University of Michigan had a course of six lectures under the auspices of a combined faculty and student committee, the course being entitled "Marriage Relations." The lectures were characterized as follows by the committee: "In this series we wish to get away from sociological and philosophical platitudes and present the facts as they are in a frank and accurate manner, making the course as practical as possible." In my discussion I followed this outline: 1. The attitudes toward discussion of sexual problems are changing, from ignorance and tabu to a demand for accurate and sane information. 2. The large number of cases of marital maladjustment and divorce constitute a challenge. 3. It is necessary to replace many fears, tabus and superstitions surrounding the physiology of reproduction and sexual practice by scientific facts. 4. Marriage must be thoughtfully considered by college students, and the information obtained by specialists who have carefully and thoroughly studied married relations must be interpreted and frankly discussed. 5. The beauty of romance is not spoiled by true understanding; rather, intelligent appreciation of important factors of emotional and sexual problems will help prevent disillusionment afterward.

DR. FRED J. TAUSIG, St. Louis: It is difficult to dissociate the purely medical aspects of birth control from its socio-

economic environment. Yet as far as it is possible and practical it is our duty as physicians to do this. Let those who are concerned with problems of population growth, with economic want, with improper education and other social phases of an uncontrolled birth rate organize, discuss and take action on these matters. How far physicians may desire to cooperate in this movement is not our concern. We are concerned, however, in the medical phases of birth control, in the cases in which the proper spacing of children, the condition of the heart, kidneys and lungs of the mother present a contraindication to pregnancy for shorter or longer periods of time. Let us as physicians recognize that this is a matter that concerns every one of us regardless of creed. Some may advise one method, others may advise a different procedure, but we all recognize the cases in which a pregnancy presents a peril to the preservation of the family, and that in married life prolonged continence is not practical. Let us all get together and attack this problem scientifically. There must be other methods besides the so-called safe period that would be acceptable to those who do not approve of mechanical or chemical procedures. Intensive research as to better methods must be carried on by all groups. Some may approve one, some another method, but the advisability of preventing conception for shorter or longer periods to preserve the mother's health is an accepted fact.

DR. JOHN ZELL GASTON, Houston, Texas: The points that have been brought up here today bring out clearly the need for scientific information on contraception. There are three questions of vital interest, namely: 1. Is birth control effective? 2. What is the relationship between birth control and abortions? 3. Is birth control dangerous? At the Maternal Health Center of Houston in the past three years we have seen 2,635 cases, and in that length of time we have not found a single one in which scientific evidence can say that birth control has been harmful. Is birth control effective? We heard one of our discussers say that birth control was not effective and that reports were made of thousands of cases of failure. Here are our results. Of 2,500 women, we have had thirty-seven failures to date, or an efficiency of 98.5 per cent. What is the relation between abortion and contraception? The answer is a negative one, like the relationship of black to white, but we were curious to find out the frequency of abortions before contraception was used; hence a careful history was taken and we have the data to offer on a study of 2,069 case histories. We divided our cases into white, colored and Mexican groups. Of 1,002 white patients, 357 admitted one or more abortions before coming to the clinic. There was a total of 615 abortions in the 1,002 white patients, and one woman admitted fifteen abortions having been done on herself. In other words, 35 per cent of the white women had had abortions before applying to our clinic for birth control. The Negro patients show practically the same ratio: Of 730 Negroes, 211 admitted a total of 354 abortions. Mexican patients have almost exactly the same ratio; namely, of 337 Mexicans, 114 admitted on admission a total of 185 abortions. Birth control clinics do not condone abortions, and any statement to the contrary is not true. On the other hand, we teach that abortions are dangerous. The need for this teaching is brought out clearly by this study. If the figures we obtained are at all representative, the frequency of abortion the country over will reach a staggering figure. Of 2,069 white, Mexican and colored married women in the low income group, 682 admitted a total of 1,154 abortions before seeking advice on contraception. Therefore we need some scientific observations on this point to separate the dogma from the fact.

DR. GEORGE W. KOSMAK, New York: There is just one item to which I should like to refer; namely, the placing of the extramural clinics on a more satisfactory foundation. As far as I know there is no formal licensing of birth control clinics and in this country these operate more or less without the pale of the law. If this question is such an important one, I believe that the profession should recognize it to the extent of providing regularly licensed clinics in hospitals. There is no need, in my estimation, for separating clinics devoted to this particular part of the practice of medicine from those of any other, and it seems to me that one of the early steps in the movement to standardize this entire procedure is to provide for more hospital clinics so that they can be kept under control and definitely managed under medical auspices.

AN EPIDEMIC OF POLIOMYELITIS

IN WHICH BULBAR PARALYSIS OCCURRED
WITH UNUSUAL FREQUENCY

ERNEST L. STEBBINS, M.D.

EDWARD E. GILLICK, M.D.

NIAGARA FALLS, N. Y.

AND

HOLLIS S. INGRAHAM, M.D.

ALBANY, N. Y.

During the two months period from July 23 to Sept. 20, 1938, twenty cases of poliomyelitis occurred in the city of Niagara Falls. However, one of the cases occurred in a resident of an adjoining town who was a frequent visitor to Niagara Falls and had had a tonsillectomy performed in that city fourteen days before the onset of poliomyelitis. There was an unusually low incidence of poliomyelitis in New York State during 1938 and the epidemic character of the series of cases in Niagara Falls is shown clearly by a comparison of attack rates in that city with attack rates in the state as a whole and in adjoining areas (table 1). The most striking features of this outbreak were the large proportion of cases in which bulbar involvement was

* Exclusive of Niagara Falls city.

observed and the high fatality rate. In thirteen of the twenty cases definite bulbar paralysis was observed and twelve of these terminated fatally, a fatality rate of 60 per cent.

CLINICAL CHARACTERISTICS

The onset of the illness was in most instances characterized by mild gastrointestinal disturbance or evidence of mild infection of the upper respiratory tract, or both. In several cases there was a lapse of several days between the first indisposition and the onset of paralysis. In the majority, however, there was a sudden onset with rapidly progressive paralysis. Marked rigidity of the neck and of the spine was observed in almost every case. As shown in table 2, spinal fluid was obtained for examination in eleven of the twenty cases and moderately increased pressure was observed in all eleven. Cell counts of the spinal fluid varied from 17 to 450. An increase in globulin was reported in nine of the eleven specimens of spinal fluid.

Extensive peripheral paralysis was the usual finding, and only one nonparalytic case was observed, although diligent search was made for mild or abortive cases. In ten of the fatal cases peripheral paralysis was followed by a rapidly progressive bulbar paralysis with respiratory failure. In one case there was no evidence of peripheral paralysis, the first evidence of paralysis being difficulty in articulation. In another case bulbar and peripheral paralysis apparently occurred simultaneously. Table 3 shows the muscle groups involved, the classification of the cases according to the type of paralysis observed and the outcome of the case.

Because of the frequency of the bulbar type of paralysis, careful inquiry was made as to previous tonsillectomy or other operative procedure in the mouth, pharynx or nasopharynx. As seen in table 3, only four of the patients had ever undergone a tonsillectomy; two of these had had the tonsillectomy four and fourteen years previously. One had been tonsillectomized four

months before the onset of poliomyelitis and one had had a tonsillectomy and adenoidectomy two weeks before the onset of poliomyelitis. No history of other operative procedures could be elicited.

ETIOLOGY

A portion of the cord and brain stem obtained at autopsy from patient 16 was sent to Dr. Charles Armstrong at the National Institute of Health, who reported that an emulsion of the material inoculated into a rhesus monkey produced paralysis and death on the seventh day and transfers to a second monkey produced typical paralysis. Pathologic study of the cord of the second monkey showed evidence of severe poliomyelitis. Three additional transfers produced typical poliomyelitis.

A portion of brain and cord removed at autopsy in case 13, also studied by Dr. Armstrong at the National Institute of Health, produced paralysis in a monkey and through three transfers tremors and paralysis were produced. Pathologic study of the tissues resulted in a diagnosis of poliomyelitis, although this strain was apparently less virulent for monkeys than the strain taken from patient 16.

Microscopic examinations in case 13 at the Division of Laboratories and Research of the New York State Department of Health confirmed the diagnosis of poliomyelitis, and inoculation of the material into a monkey produced typical experimental poliomyelitis; further passage through a second animal gave similar results. Histologic appearances in both monkeys were those of poliomyelitis. Nasal washings from patient 17, obtained on the sixth day of illness, were sent to Dr. Armstrong, who reported that this material filtered and inoculated into a rhesus monkey failed to produce symptoms.

EPIDEMIOLOGIC EXAMINATIONS

Twelve of the cases occurred in males and eight in females; the ages varied between 4 months and 21 years. Twelve of the patients were 5 years of age or younger and all but three were under 10 years of age. Seven of the cases were in children of Italian descent and four were in children of recent descent from other European

nationalities. There was a rather definite geographic grouping of cases in the city. Ten of the cases occurred within a radius of three city blocks and all but two occurred in persons residing within ten blocks of the Niagara River. This did not, however, constitute a definite concentration of cases near the waterfront, because the city is located at a bend in the river and is distributed along both arms of the angle. The economic status of the families in which cases occurred was in general a little below average, but in none was there evidence of great poverty. The children suffering from the disease almost invariably were especially healthy and well nourished prior to the illness. No history of direct contact between the patients was obtained, but in a number of instances friends were found to have been common to more than one patient. No multiple cases occurred in any household nor were there any suspicious illnesses among contacts of the patients. In only one instance was there a history of previous poliomyelitis in the immediate family, and in one there was a history of poliomyelitis in a first cousin several years previously.

No one milk supply was found to have been used by any disproportionate number of the patients. The usual water supply in all but one case was the municipal supply. In less than one third of the cases a history of recent use of a bathing beach or swimming pool was obtained and various bathing places were used by these. No history of recent insect bites was obtained in any case. Many of the patients, however, had died by the time the epidemiologic investigation was made, and the history obtained from the parents, although apparently given much thought, is open to question. Mosquitoes were prevalent at the time of the outbreak and were apparently more prevalent than is usual at that season.

TABLE 3.—*Muscle Groups Involved and Clinical Classification in Niagara Falls of Poliomyelitis, 1938*

18	0	+	+	0	0	0	Spinal	Died
19	+	+	0	0	0	+	Bulbospinal	Died
20	+	+	+	+	0	+	Bulbospinal	Died

+ Indicates definite positive signs; 0, no evidence of paralysis.
? Recovered with residual paralysis.

This unusual prevalence of mosquitoes was observed, however, in other areas in the state. Several parents, when questioned as to prevalence of insects or vermin, remarked that an unusual number of spiders had been observed. In no instance was there a known close association with horses. Cats and dogs were associated as pets in several instances, but no definite evidence of association of more than one case with the same pet was observed. No evidence of rat infestation of homes was noted.

SUMMARY AND CONCLUSIONS

A definite epidemic prevalence of poliomyelitis occurred in the city of Niagara Falls during July, August and September 1938. Clinical and laboratory observations confirmed the diagnosis of poliomyelitis.

Thirteen of the twenty cases showed evidence of bulbar paralysis; twelve of these cases terminated fatally.

In only two of the cases classified as bulbar in type had a tonsillectomy ever been done, one two weeks preceding the onset of poliomyelitis and one four years preceding the onset. No other operative procedure in the mouth, nose or throat had preceded the poliomyelitis in these cases.

No evidence of direct or indirect contact between cases could be elicited, but there was a distinct grouping of cases in a limited area. No factor in the environment was found to be common to any large proportion of the cases other than the water supply.

Clinical Notes, Suggestions and New Instruments

PREGNANCY COMPLICATED BY ACUTE ANTERIOR POLIOMYELITIS

JOSEPH R. MORROW, M.D., AND SANFORD A. LURIA, M.D.
RIDGEWOOD, N. J.

Little has been written on pregnancy complicated by acute anterior poliomyelitis. This is especially true of case reports that were followed to term and through parturition. One of the most recent articles on this subject was published in July 1933 by Brahdy and Lenarsky,¹ in which three cases were reported which were followed post partum. The summary of eight previous cases was also given. It is likely that a few other similar cases may not have been reported. Nevertheless, the incidence of epidemic poliomyelitis during pregnancy is probably rare.

This case is of particular interest not only because of the unusual and hazardous complications of gestation but also because of the many problems which were encountered relative to the disease process per se. Some of the questions for consideration were (1) viability and effect of this disease on the fetus, (2) the antiviral power of the fetus toward this disease, (3) type of delivery necessary, (4) whether surgical intervention would be advisable prior to term and (5) effects of the muscle atony on the parturient canal and bony pelvis.

In the eleven cases previously reported, delivery of the child was spontaneous in most instances, although there were two cesarean sections and one therapeutic abortion. The newborn infants were not infected by the poliomyelitis virus, although there was one stillbirth in which no evidence of this disease was shown but death was due to prematurity.

There are two schools of thought regarding the occurrence of poliomyelitis in pregnant women. Aycock² is of the opinion that poliomyelitis may occur more frequently in the latter part of pregnancy than would normally be expected if this condition had not been predisposed to the disease. On the other hand, Jungeblut and Engle³ state that both early pregnancy and infancy are the high water marks of natural resistance to poliomyelitis. Their accounts were based on the results of the examination of blood from several women during various stages of pregnancy. They found higher antibody titers than are

commonly found in healthy, nongravid persons. McGoogan⁴ in 1932 published an article on three cases of pregnancy complicated by poliomyelitis and also the results in five similar cases which were reported in the literature during a period of twenty-five years. This is the first case of its kind in this hospital since its inception twenty-three years ago.

REPORT OF CASE

History.—E. W., a woman aged 28, was admitted to this institution Aug. 16, 1938, by transfer from one of the near general hospitals. She had had measles, epidemic parotitis and varicella; otherwise the past history was not remarkable. The patient was married; her husband and one child were living and well. Her father and mother were both living and well.

One week prior to admission, the patient complained of severe headache and felt "feverish." This condition was followed in a short time by nausea and vomiting. The family physician was called and made a tentative diagnosis of meningitis, based on the meningeal manifestations. The patient was immediately sent to a general hospital, where a spinal tap was performed and meningococcus serum was introduced intrathecally, as is customary in many institutions in cases of suspected meningitis. Twenty-four hours later she noticed an inability to move her legs and complained of severe pain through both lower and upper extremities and the lumbosacral region. She also gave a history of being unable to void urine or defecate. She was then transferred to Bergen Pines. It was further learned from the history that she had been gravid for five and one-half months. Cessation of menses occurred in the month of March, approximately five months prior to admission.

Physical Examination (by systems at time of admission).—The patient was found to be well developed and well nourished. She appeared very lethargic and responded poorly to questions, although answers were coherent. Her face was flushed, the skin moist and smooth, and there was no evidence of any eruption over the entire body.

The eyes were normal except that the pupils were dilated slightly more than normal. There was slight deviation of the septum to the left. The pharynx was mildly injected. The tonsils were atrophic and submerged. There were slightly palpable anterior and posterior cervical glands.

The heart sounds were distinctly audible over the entire precordium. No adventitious sounds were heard. There was moderate tachycardia. Respiratory excursions were diminished, more noticeably on the right side. The breath sounds were heard clearly throughout the upper two thirds of the chest and slightly diminished over the bases, especially anteriorly. No rales were heard.

The abdomen was markedly distended and the uterus could be palpated, extending from behind the symphysis to three finger-breadths below the umbilicus. There was a tympanitic note heard on percussion over the entire abdomen, except for the lower third, which was dull because of retention of urine in the bladder. Tenderness was elicited over both costovertebral regions. The fetal heart sounds were heard with difficulty; and the rate could not be determined.

The neck was markedly rigid. The pupils were slightly dilated but reacted to light and in accommodation. The ophthalmoscopic examination revealed normal fundi. The right palatine muscles were paralyzed. The pharyngeal reflex was diminished and phonation impaired. The intercostal group of muscles were weak bilaterally, as evidenced by the diminished respiratory excursion, more so on the right. The abdominal reflexes could not be elicited. Peristaltic or borborygmnic sounds could not be heard in spite of marked distention. There was no muscular contraction on voluntary effort. There was also paralysis of the lumbosacral group of muscles.

There was weakness and partial paralysis of the arm, forearm and shoulder girdle of both upper extremities. There was complete flaccid paralysis of both lower extremities from the trunk line down. In addition, there was involvement of the autonomic nervous system as related to the gastrointestinal tract and the urinary bladder, resulting in an inability to defecate and void.

Kernig's sign was positive bilaterally. Both patellar and achilles reflexes were absent. Babinski, Oppenheim, Gordon

The authors were aided by Dr. William Tompkins, who cooperated in this case.

and ankle clonus were all negative. Biceps and triceps reflexes were also negative. The Hoffman sign was negative.

Since the paralysis was ascending, beginning with the lower extremities and progressing upward, it was very similar to Landry's type. A diagnosis of acute anterior poliomyelitis, early paralytic stage, superimposed on a five and one-half months pregnancy, was made from the results of the foregoing examination and the confirming spinal fluid report, which will be given along with other laboratory data.

On admission August 16 the urine was normal. Blood examination revealed 3,870,000 red blood cells, hemoglobin (Sahli) 80 per cent, 11,250 white blood cells, polymorphonuclears 85 per cent, lymphocytes 14 per cent, mononuclears 1 per cent.

A throat culture was positive for hemolytic streptococci.

As the result of a spinal tap, opalescent fluid was removed under slightly increased pressure with 180 cells: polymorphonuclears 48 per cent, lymphocytes 52 per cent, globulin reaction 2 plus, sugar 74 mg. per hundred cubic centimeters. Chloride determination was not done. The spinal fluid report obtained prior to the patient's transfer was similar.

Course.—This was very stormy, owing to the patient's extreme toxemia and the extensive paralytic involvement. Her facies, which was very conspicuous, varied from marked apathy to extreme apathy.

On the second day following admission the patient had a chill, the temperature rising to 106 F. At this time she became irrational. Fortunately, this condition was transitory in nature and the patient regained her mental clarity within twenty-four hours. The gastrointestinal atony, simulating a paralytic ileus, and the associated distention, which was very resistive to almost all remedial agents, contributed greatly to the respiratory embarrassment, which had already been hampered by partial paralysis of the intercostal and diaphragmatic muscles. Bowel evacuation was obtained only by daily enemas. Frequent catheterization was necessary owing to rapid filling of her temporarily denervated bladder. In the following few days there developed a urinary tract infection which, along with the toxemia, caused a continuation of the septic type of temperature, which ranged between 101 and 104 F. for a period of sixteen days. Blood studies at this time revealed a hypochromic anemia, which further complicated the clinical course. This iron deficiency anemia was unlike the usual anemia associated with pregnancy in that it was very resistive to therapy. Massive doses of ferric and ferrous salts in the form of sulfate, carbonate and ammonium citrate were given at different times with no apparent response. Liver and vitamin B₁ were then given, along with the iron salts, but these also were of no substantial value. Multiple transfusions were necessary to help maintain the hemoglobin and red blood cells at a fairly constant level, in spite of which they remained slightly subnormal. We attributed this anemia not only to the pregnancy but also to the toxemia, which may have partially exhausted the hemopoietic system. Hemoglobin levels ranged between 50 and 77.

August 28, blood examination revealed 3,190,000 red blood cells, hemoglobin 61 per cent, 20,900 white blood cells, polymorphonuclears 90 per cent, lymphocytes 8 per cent, mononuclears 1 per cent, basophils 1 per cent. The polymorphonuclear cells showed toxic granules.

Urinalysis at this time revealed the specific gravity to be 1.010, acid reaction, a heavy trace of albumin, pus clumps, and many white blood cells and bacteria.

The patient's condition was considered critical for eighteen days. Following this period she started to show gradual and progressive improvement. The temperature returned to within normal range. The abdominal distention, however, continued to cause her discomfort frequently, but less so than previously. Within the following four weeks it was noticed that there was some muscle restoration in both upper extremities, the chest and the trunk. There was a return of bowel and bladder function to voluntary control. The pyelitis improved but still showed occasional pus clumps and traces of albumin in the daily specimens of urine. The blood pressure, which had been 160/90, finally became 138/85. It was possible that the poliomyelitis had begun to precipitate a preeclamptic state earlier in this disease.

The remaining course in the hospital was comparatively uneventful. During the entire stay of the patient in the hospital the fetal heart sounds could be heard and movements could be felt both objectively and subjectively. The size of the gravid uterus reached to one fingerbreadth above the umbilicus prior to discharge.

Treatment.—Although the value of convalescent serum is still controversial, there have been some encouraging reports following the administration of large doses of serum intravenously early in the disease. Our own experience with convalescent serum has always been of doubtful value. Nevertheless, the patient was transfused with the blood obtained from an adult who had recovered from this disease. It was believed that it would therefore serve a twofold purpose (1) as a therapeutic for the toxemia and (2) for possible specific antibody effect. The specificity of this procedure was doubtful.

Vitamin B₁ and C parenterally was also given, as this form of treatment has been suggested more recently by various workers in this field. Vitamin B₁ intraspinally, as suggested by Stern⁵ in one of his recent reports, was decided against, as we feared the possibility of further meningeal irritation and development of a chemical meningitis, which one of us (S. A. L.) has observed. The remaining treatment consisted essentially of hypertonic intravenous infusions in the form of 50 per cent sucrose, spinal taps as indicated, multiple transfusions, iron and liver therapy, ultraviolet radiation and other symptomatic and supportive measures. The orthopedic care was limited to immobilization of the involved members, followed three months later by very gentle massage therapy.

Although the patient was discharged with the understanding that she should be further hospitalized for orthopedic and obstetric care, she preferred to remain at home under the care of her family physician and obstetrician for economic reasons. The course while at home, as related to us by her family physician, was also uneventful except for the persistent anemia.

December 20 the patient suddenly experienced labor pains and was immediately rushed to the hospital. The labor progressed rapidly and it was felt then that she might precipitate. On arrival at the hospital she was taken immediately to the delivery room and delivered a 6 pound (2,720 Gm.) living girl baby in apparently good condition. The delivery itself was rather simple, although it required forceps and episiotomy.

Her postpartum course was also uneventful. In spite of an apparently lowered resistance, no puerperal infections developed. She had received three transfusions and her blood picture returned to normal within three weeks. The infant's condition remains good up to the present writing, showing no evidence of paralytic involvement.

COMMENT

In reviewing the case, one is inclined to believe that the antiviral titer toward poliomyelitis in gravid women does not differ from that of other adults who may contract this disease. However, this is not true, apparently, as it has been pointed out that the incidence of poliomyelitis during pregnancy is relatively low. The fetus perhaps does not contract the disease, as the virus probably does not enter the placental circulation. However, there has been a case report by Lance⁶ of poliomyelitis in the newborn, but the evidence presented is inconclusive and there was no history of an acute infection during the course of pregnancy. If death does occur to the fetus, it is probably due to the toxemia which accompanies poliomyelitis, rather than to the virus per se.

With regard to the parturition, there is apparently no variation from other paraplegias due to other causes such as spinal cord tumor or trauma except that, in the latter, labor is painless, although in cases with respiratory involvement cesarean section may be indicated before term if the increasing size of the uterus further hampers respiration. Also in those cases of bulbar involvement in which death is imminent a cesarean section should be done immediately after the patient's death to save the viable fetus.

5. Stern, E. L.: The Intraspinal (Subarachnoid) Injection of Vitamin B₁ for the Relief of Intractable Pain and for Inflammatory and Degenerative Diseases of the Central Nervous System, *Am. J. Surg.* 33:495 (March) 1938.
6. Lance: Infantile Paralysis Noted at Birth, *Bull. Soc. de pediat. d. Paris* 31:229 (May) 1933.

This case differs from most of those that have been reported because of the extensive involvement which, unfortunately, the patient encountered because of her relatively high susceptibility and other complications which developed relating to both pregnancy and poliomyelitis. Nevertheless it is encouraging to learn further that these women can deliver normally and also give birth to healthy infants.

Blood studies of the child and the mother for neutralization against the poliomyelitis virus have been determined. The laboratory results of the tests on the newborn babe show that she carries poliomyelitis neutralizing antibodies in such amount that 0.2 cc. neutralized about 25 minimal infective doses of virus in an exposure of two hours at 37 C. followed by an overnight temperature of 4 C.⁷

The mother's blood, which was studied six months following the acute onset of the disease, showed a very high antiviral blood content, as the control monkeys developed acute anterior poliomyelitis eleven days after intracerebral inoculation, while those injected with the serum virus mixture remained healthy. The laboratory procedure in the latter instance was done merely to determine whether the patient may have lost any of her immunity since the onset of the disease.

GROUP COLOR VISION TESTS

CONRAD BERENS, M.D., AND LESTER STEIN, M.D., NEW YORK

The desirability of including routine color vision tests in all eye examinations is widely recognized. Of particular importance is the evaluation of the color vision of civil service applicants, motor vehicle licensees, mariners, railway employees and others whose occupations require normal color vision. Routine school examinations should include some form of color vision testing, but the necessity of examining large classes has frequently led to the omission of color vision testing. The regular physical examination for the military services includes rigorous color vision tests.

When large groups of persons are involved, color vision tests by the present methods are usually arduous and expensive and require the services of numerous examiners. Therefore the need for quick, accurate, acceptable color vision tests of large groups of persons is evident.

METHOD

The method to be described apparently fulfils the requirements for color vision tests for large groups of subjects. A search of the literature from 1929, when color photography became more accurate, reveals no mention of this method. It employs among other tests the standard pseudo-isochromatic Ishihara or Stilling charts, which are world accepted for testing color vision. The published color vision charts are copied with Kodachrome film and then made into colored lantern slides. These colored lantern slides can be made in miniature size by employing the 35 mm. Kodachrome film. The copies can be made with any of the usual miniature cameras available in conjunction with the manufacturer's recommended copying accessories. In this way 2 by 2 inch miniature lantern slides are obtained. These are suitable for projection in any of the special miniature lantern slide projectors. The image projected is just as large, clearly defined and of good color value as that projected with the large lantern slide projectors. For those wishing to use the large lantern slide projectors, however, it is also feasible, but more expensive, to employ 3¼ by 4¼ inch sheet Kodachrome film and make large slides for use in the large projectors. The larger slides afford no advantage over the miniature slides. For best projection results glass bead screens should be employed. Many models, both of fixed and of portable types, are available commercially.

This projected test has been used in testing color blind persons and the results have been compared with a similar test employing the original test plates. It was found that the results were identical.

7. Neutralization tests for poliomyelitis by Dr. John Kolmer, Research Institute of Cutaneous Medicine.

Aided by a grant from the Ophthalmological Foundation, Inc. Presented before the Section on Ophthalmology, New York Academy of Medicine, April 17, 1939.

From the Department of Research of the Lighthouse Eye Clinic of the New York Association for the Blind.

TECHNIC OF EXAMINATION

In actual use the test is performed as follows: The subjects are seated in a suitable projection room, semidarkened to permit a good view of the screen, and each is supplied with a printed schema containing key numbers corresponding to the slides, which are projected on the screen in order. The subjects are required to write the figure that they identify on the pseudo-isochromatic chart projected on the screen next to the key number on the schema. The written responses may be rapidly totaled by matching them with the master record, and a quick estimate of color vision can be made and duly recorded. This permanent record may be kept for future comparisons to be written in adjacent columns.

ADVANTAGES

The advantages of the method are the ease with which the tests are performed on large groups of subjects and the small expense involved. A few examiners can determine the color vision of thousands of subjects in much less time than has hitherto been required.

Permanent self-written records are obtained and repetition of the test is fairly simple and easily carried out and can be performed as part of an annual examination.

Easy interchangeability of the various color tests is afforded because one can employ Ishihara or Stilling charts or other forms of pseudo-isochromatic charts with equal facility by merely altering the order of the slides.

The malingering tests included in the Ishihara and Stilling plates, the threshold tests after the Young method, the Edridge-Green and other lantern tests, the Worth four dot test¹ and its modifications² and the kindergarten chart with colored figures³ may be similarly projected.

Visual acuity need not be normal, since it is easy to magnify the images by projection and thus obviate errors occasioned by subnormal vision of moderate degree.

Disturbances of color vision which are found in certain diseases, e. g. toxic amblyopia, optic neuritis and retrobulbar neuritis, may be revealed.

Motor vehicle license control is facilitated greatly by this method of testing large groups of licensees.

For the testing of illiterate subjects and young children, charts have been constructed employing the international broken ring, the illiterate E or the Snellen pronged figure. In addition, for little children pseudo-isochromatic tests may be drawn using kindergarten figures such as animals, toys, men, dogs, boats and similar easily recognized objects placed on a confusion color background. A method of constructing these charts simply has been devised and is being studied at the Lighthouse Eye Clinic.

An important corollary of this method is the possibility of employing projected color slides of various scenes, objects and charts to educate color blind persons to differentiate various colors and by association teach them to adapt themselves to their environment.

In addition, it is feasible to include the test in any of the projector type visual acuity apparatus now available, for example the Ferree-Rand visual acuity projector or the projectoscope, and thus increase the field of usefulness of these machines and provide satisfactory office color vision tests.

SUMMARY

In a method for testing large groups of subjects for disturbance of color vision the Kodachrome film is employed to make colored copies of the Ishihara or Stilling or newly constructed charts in either miniature (2 by 2 inch) or regular (3¼ by 4¼ inch) sizes.

Projection of the slides yields good images, readily perceived in large audience halls and thoroughly satisfactory for the testing of the color vision of large groups of subjects.

The advantages include ease of testing, small expense and permanent records, written by the subject himself. Disturbances

of color vision, which would suggest further studies for the diagnosis of certain diseases, may be revealed by these mass color vision tests. This method of testing greatly facilitates the examination of drivers of motor vehicles, aviators, railroad employees and applicants for the army, navy and marine services. Forms of the pseudo-isochromatic color vision tests, employing illiterate and kindergarten figures and the international broken ring, are being developed.

The possibility is suggested of educating color blind persons to differentiate colors by demonstrating colored scenes and charts.

WOOD TICK SIMULATING PEDUNCULATED TUMOR

KURT WIENER, M.D., MILWAUKEE

Ormsby writes that the female of the wood tick (*Ixodes*) after sucking blood from the skin swells to the size of a pea or a small bean and may be mistaken for a small pedunculated tumor. How true this is may be illustrated by the case reported here.

Fig. 1.—Appearance of patient's chest.

An elderly man who has a number of partly pedunculated and pigmented senile keratomas and fibromas on his chest (fig. 1) complained that one of them started to burn and itch. At first glance the little tumor did not look especially different from the others. When viewed more closely (fig. 2) the coffee bean size tumor was found to have eight legs and proved to be a wood tick (*Ixodes*) which the patient had picked up in the woods of

Fig. 2.—Close view of object indicated by arrow in figure 1.

Fig. 3.—Wood tick with beak buried in skin.

Northern Wisconsin two weeks previously. The tick, apparently aware of the high value of good mimicry and well acquainted with Ormsby's textbook, had chosen a human skin with little tumors where it could partake of its sanguinary meals with much less danger than on a normal skin. A drop of turpentine helped to remove it. Figure 3 shows how its beak is buried in the skin.

425 East Wisconsin Avenue.

INTESTINAL OBSTRUCTION CAUSED BY COLLOIDAL ALUMINUM HYDROXIDE

W. PAUL HAVENS, M.D., PHILADELPHIA

Colloidal aluminum hydroxide has been widely used for the treatment of peptic ulcer since Crohn reported its value as an antacid in 1929. There has been little information available concerning any untoward effects. Kraemer¹ described frequent constipation and the occurrence of fecal impaction in two cases, but the majority of observers have not mentioned such complications.

The following case illustrates the danger which exists and the unfortunate result which may occur when colloidal aluminum hydroxide is used in the treatment of certain cases of bleeding duodenal ulcer.

M. F., a Negro woman aged 59, a widow, was admitted to the hospital complaining of generalized weakness and intermittent pain in the lower part of the abdomen of two weeks' duration.

There was moderate enlargement of the heart, and the blood pressure was 180 systolic and 110 diastolic. She was treated for hypertensive cardiovascular disease for three weeks. At the end of this time an episode occurred which suggested a sudden internal hemorrhage. She became weak and restless and the mucous membranes appeared pale. The blood pressure fell to 110 systolic and 60 diastolic, and the pulse rate rose to 138. The hemoglobin content and the red cell count, which had been 80 per cent and 3,850,000 respectively, fell to 30 per cent and 1,000,000. Several unformed stools were tarry. She was given frequent feedings of gelatin water and gruel with 8 cc. of colloidal aluminum hydroxide every two hours for three and one-half days. A tube was then placed in the stomach, and a constant drip of two parts water and one part colloidal aluminum hydroxide was allowed to flow in at a rate of 2,000 cc. in twenty-four hours. To this was added 160 cc. of corn syrup (karo) for two days. The patient remained in poor condition in spite of frequent transfusions of blood. Bleeding from the bowel continued and she failed to gain strength. Although she was given liquid petrolatum only once, enemas were effective at least every other day and frequent examinations for fecal impaction gave negative results. Because of restlessness, morphine sulfate 10 mg. was administered every four hours for a few days. After seven days of treatment with the constant drip the abdomen became distended and no peristalsis was heard. A diagnosis of intestinal obstruction was made. Suction was applied to the tube in the stomach and 1,900 cc. of greenish yellow fluid was obtained, which reduced the distention slightly. An enema caused the evacuation of a moderate amount of tarry material. Her condition became progressively worse and she died a few hours later.

At necropsy the characteristic changes of arteriosclerotic cardiovascular-renal disease were noted. The heart was slightly enlarged and there were moderate atherosclerotic changes in the arteries. Immediately adjacent to the pyloric sphincter in the duodenum there was an ulcer measuring 3 by 1.2 by 0.4 cm. The jejunum and proximal two thirds of the ileum were distended with gas. Beginning at about the midportion of the ileum, the lumen contained a semisoft putty-like material which in the distal portion became more inspissated, until firm casts of the bowel were formed which caused total obstruction. Immediately distal to the ileocecal valve was a large globular mass of the same material mixed with inspissated blood, approximately 7 by 8 cm., forming a partial cast of the cecum. Lumps of similar material about 2 by 6 cm. in size were present in the remainder of the cecum and transverse colon. Beginning at about the midportion of the transverse colon several hard reddish black masses measuring approximately 2 by 5 cm. were present, and these became larger in the descending colon, sigmoid flexure and rectum.

COMMENT

Reports on the constipating effect of colloidal aluminum hydroxide and the occurrence of fecal impaction following its use are infrequent. The preparation used (amphogel) contains

From the Department of Medicine, Jefferson Medical College Hospital.

about 5 per cent aluminum hydroxide, which, combined with the astringent effect produced, may favor constipation, especially when there is blood in the intestine. It is possible that the frequent use of liquid petrolatum and enemas by the vigorous young adult may lessen the danger of this complication, but there appears to be a danger in administering aluminum hydroxide to older or very ill patients, whose energy is depleted and whose intestinal tract may lack normal tonus. As a further precaution, morphine sulfate, because of its alleged depressant action on the bowel, should be used only with caution. It is possible that the gelatin given together with the aluminum hydroxide aided in forming firm masses.

Special Clinical Article

THE SURGICAL ASPECTS OF CARCINOMA OF THE STOMACH

CLINICAL LECTURE AT ST. LOUIS SESSION

ALFRED BROWN, M.D.

OMAHA

Over the seven year period from Jan. 1, 1931, to Jan. 1, 1938, there have been 10,458 deaths from cancer of all forms in the state of Nebraska. The figures for 1938 are not yet available. Of these deaths cancer of the digestive tract and peritoneum furnished 5,519, or a little more than half the total deaths from cancer (table 1). The facilities of our state health department do not enable a complete breakdown of site and organ, but it is reasonable to assume that from one third to one half of the deaths from cancer of the digestive tract and peritoneum are due to cancer of the stomach. This makes approximately 2,000, or one fourth, of the deaths from cancer of all forms due to carcinoma of the stomach. With these facts in mind, it seemed worth while to make a study of the situation regarding cancer of the stomach as we see the disease in the Hospital of the University of Nebraska School of Medicine, as this institution receives patients from the entire state.

In order to evaluate these cases, the histories of all cases of cancer of the stomach in the University Hospital between Jan. 1, 1931, and Jan. 1, 1939, were gone over and classified under headings that were selected to give the best idea of the condition of the patient at the time of admission and discharge. The histories in these cases were taken by first year interns who are serving on a one year general rotating intern service. Consequently the histories are not particularly detailed or directed especially to obtaining symptoms due to disturbance of the gastrointestinal tract and are in no way specialized along this line. They do, however, give interesting information and should be a true comparison with histories which could be elicited by the general practitioner.

There have been eighty cases of cancer of the stomach admitted to the University Hospital during the eight year period and the statistics regarding these cases have been arbitrarily divided into two periods. The first, from Jan. 1, 1931, to Jan. 1, 1936; the second, from Jan. 1, 1936, to Jan. 1, 1939. This arbitrary line was chosen for two reasons: first, because the first division represents a five year period and, second, because 1936 represents the first year in which a patient suitable for resection of the growth in the stomach entered the Uni-

versity Hospital. All the cases in the first five year period were so far advanced that resection was technically impossible.

In the first group there were thirty-two males and nine females, and in this group it will be noted that the greater percentage occurred in the 50-59 year decade (table 2). In the second group there were twenty-five males and fourteen females (table 3). When, however, all cases were classified according to sex it will be noted that the majority of our cases in women occurred during the sixth decade while during the preceding and following decades the number is markedly diminished (table 4). In men the occurrence of the disease is spread over the sixth and seventh decades with a marked falling off toward the earlier decades and a lesser falling off in later years.

In the largest percentage of cases the cancer was in the prepyloric region of the stomach, the lesser curvature was next and the cardia and greater curvature in the smallest percentage of cases.

In the first group, seventeen of forty-one patients complained of premonitory symptoms over periods of from six months to twenty-five years. This period was computed from the time the patients were admitted to the University Hospital and a definite diagnosis of cancer was made.

The premonitory symptoms are shown in table 5 and only those symptoms which were directly referable either to cancer or to some abdominal condition were selected to be included in the summary.

In the second group of thirty-nine patients, thirty-one complained of premonitory symptoms over periods varying from five months to thirty years (table 6). The larger percentage of patients complaining of premonitory symptoms in this group may be due to the fact that the interns were more careful in history taking because, knowing of this investigation, they were more alert in inquiring about gastric symptoms. The type

TABLE 1.—Cancer Deaths in the State of Nebraska

1937.....	1,557	798

of premonitory symptoms calls attention to the controversy as to whether or not cancer develops on ulcer. This question has in past years divided pathologists into two groups: those who believe that cancer develops on an ulcer base and those who believe the contrary. It is not in the province of the clinician to enter into this discussion from the histologic basis. From the clinical standpoint this investigation shows that of a total series of eighty patients forty-eight, or more than 50 per cent of the patients, complained of definite or indefinite abdominal symptoms over a period of from five months to thirty years. In some of the cases a diagnosis of ulcer of the stomach or duodenum had been made and in some the statement had been made that this ulcer had been cured. Consequently, from the clinical standpoint the active symptoms of carcinoma of the stomach are preceded in many instances by a train of either definite or indefinite abdominal symptoms over a considerable period of months or years preceding the development of cancer itself.

Our results show that the patient with cancer of the stomach who presents the classic symptoms and clinical evidences of the disease at the time of entrance into the hospital usually has a carcinoma so advanced that surgical aid is at the best extremely hazardous and in the great majority of cases any surgical attack is contra-indicated.

60 to 69 years.....	11 cases
70 to 79 years.....	4 cases
80 years and over.....	1 case

In the first five year series of forty-one cases we were unable to find any case suitable for radical resection of the carcinoma.

In the second group, of thirty-nine cases over a period of three years, radical operation was performed on seven patients. One of these patients was still living ten days ago:

A man aged 74 had had abdominal pain off and on for thirty years and entered the hospital because he had had nausea accompanied by vomiting of everything he ate for six weeks and during this period had been bedridden. During his period of bed confinement he had lost between 15 and 20 pounds (7 to 9 Kg.). He had only a moderate grade of anemia, with 80 per cent hemoglobin. He had some free hydrochloric acid in the last three specimens of the fractional gastric test. He had a palpable mass in the abdomen, and at operation what was thought to be an annular carcinoma of the prepyloric region was found. A Billroth I operation was performed. The operation was complicated by a parotitis which did not require surgical drainage and he was discharged from the hospital after a six weeks stay. A report from his physician states that on May 6, 1939, he weighed 146 pounds (66 Kg.), a gain of 16 pounds (7 Kg.) over his hospital admission weight. At the present time he has occasional attacks of abdominal cramps which yield to digestive remedies.

50 to 59 years.....	14 cases
60 to 69 years.....	11 cases
70 to 79 years.....	11 cases

Unfortunately, the specimen removed from this patient was lost and a histologic examination was not made. It must, therefore, remain a question as to whether this was actual cancer or callous ulcer without malignant change. The other surgical patients all died within a year and there were three postoperative deaths in periods of from three to ten days following operation.

One other case appeared to be suitable for resection but operation was refused. In six cases exploratory

operation was performed and an inoperable carcinoma found. In two cases gastro-enterostomy was performed and death occurred in one three months after operation; the other has not been traced. Consequently the result of surgery in these eighty cases reveals one patient alive and apparently well ten months after operation, and there is some doubt whether this patient had a carcinoma.

METHODS OF TREATMENT

The operations performed in these cases were different types of procedure and were directed toward the mechanical condition of the carcinoma when examined with the abdomen open. In one case the lesion was thought to be benign at the time of operation and a gastro-enterostomy was performed for what was considered to be a prepyloric ulcer. A resection was not performed at the time because of the poor condition of the patient but examination of the specimen showed definite adenocarcinoma. After a further period of preparation a resection of the pylorus was performed and the patient lived for eight months. Autopsy showed metastatic carcinoma of the liver. In two cases the Billroth I operation was performed. One of these patients died from peritonitis six days after operation. Autopsy showed an unsuspected Krukenberg tumor of

the ovary, with peritonitis due to perforation at the site of operation. In the remaining cases subtotal gastrectomy of the Polya type was performed. The longest period of life after this operation was nine months. During this period the patient had had practically no gastric symptoms. He had gained weight but succumbed to kidney complication following acute prostatic obstruction for which he refused operative relief. He died at his home in the western part of the state and an autopsy was not obtained.

A prominent symptom in the great majority of these cases in which blood examinations are available has been a grade of anemia which could not be accounted for on the basis of hemorrhage. This finding has been so constant that the presence of a marked anemia in a middle aged person without definite cause should call attention to the stomach as a point of attack for detailed investigation. Other symptoms studied—pain, loss of weight, absence of free hydrochloric acid and the appearance of occult blood in the stools—have been present in this series of cases in the same proportion as in other series.

A study of the observations in this series of cases raises the question whether the medical treatment of gastric ulcer is justified from the fourth decade of life on. Every patient is entitled to one attempt at medical cure of gastric ulcer. A recurrence of symptoms of ulcer after one medical regimen should raise the question as to the advisability of surgical exploration. If surgical exploration is carried out and a prepyloric

ulcer found it should be removed if technically possible in preference to the performance of a palliative drainage operation. We have a specimen in our laboratory of the development of carcinoma in the base of a healed ulcer. We have many specimens of carcinoma developed on ulcer. Consequently it still remains a question

whether ulcer remaining in the stomach, even though it gives no symptoms, may not be a source of potential danger to the patient.

The type of operation performed should be the one most suitable to the type of ulcer encountered at operation. As an illustration I cite two cases which are my oldest living examples of patients in the cancer age whom I have recently followed up.

A woman, married, a school teacher, 52 years of age at the first admission, who was admitted to the hospital Aug. 14, 1926, at that time complained of indigestion, ushered in with an attack of intense nausea three years previously. A few months after the onset she complained of severe pain of the hunger type. She entered the hospital for Sippy treatment. On admission, free hydrochloric acid was 67, total 93. On discharge, free hydrochloric acid was 45, total 59. She had occult blood in her stool on two examinations, none for the remainder of her stay. She was discharged seventeen days after admission in an improved condition. She reentered the hospital Aug. 12, 1927, with the history that after leaving the hospital she felt much better. She had a gastric hemorrhage in the spring of 1927 followed by tarry stools. She had been on a diet for four years and she thought that these attacks were brought on by worry. Blood examination revealed 4,580,000 erythrocytes, 10,200 leukocytes, hemoglobin 79 per cent. A fractional gastric analysis showed an increase in free hydrochloric acid. The stool showed constant occult blood varying from 2 to 4 plus. X-ray examination showed an ulcer of the perforating type in the middle third of the lesser curvature of the stomach. The duodenal cap was deformed by scars resulting from old ulcers. August 22, a V shaped resection of the lesser curvature of the stomach including an ulcer of the perforating type about 1 inch by 1 inch in size was performed. Following operation the patient developed bilateral suppurative parotitis necessitating opening of both parotid glands. She finally made a good recovery and was discharged Oct. 12, 1927. She reentered the hospital Dec. 21, 1929, with the symptoms of hyperthyroidism. The goiter was removed by subtotal thyroidectomy and she made an uneventful convalescence. So far as gastric symptoms are concerned, she remains well today and carries on her work as a teacher. It is now eleven years and nine months after her gastric operation. A roentgenogram of the patient's stomach taken one year ago shows a markedly shortened lesser curvature, but it is apparently functioning sufficiently well to carry on normal digestion. It is to be noted that this was an ulcer in a woman in the sixth decade of life, at the time when

most carcinoma develops. No evidence of carcinoma, however, was present in the ulcer removed at operation and no glandular enlargement was demonstrable.

A man aged 61 at the time he was first seen in June 1930, married and an educator, complained of severe pain in the epigastrium coming on in attacks which simulated gallbladder colic. X-ray examination showed no shadow of the gallbladder with the Graham Cole test, and the gastrointestinal tract appeared to be normal. Temperature, pulse and respirations were normal. The heart and lungs were normal. There was moderate tenderness in the epigastrium. No respiratory catch occurred on inspiration, and no masses were felt in the abdomen. In June 1930 he was operated on. The gallbladder was found to be normal with no adhesions. There were dense adhesions between the hepatic flexure and the liver. Beneath these the great omentum was plastered to the upper surface of the pylorus and the under surface of the liver. Beneath these there was an area on the prepyloric surface of the stomach, one-half inch in diameter, surrounded by an area of redness and infiltration. Palpation through the stomach wall revealed the crater of an ulcer in the area of redness. In the gastro-hepatic omentum was a lymph gland, intensely hard and about the size of a buck shot. Under local anesthesia a "Finney" pyloroplasty, including the ulcer and a considerable area around it in the incision, was performed. The lymph gland was also excised. From all indications this appeared to be a case of prepyloric ulcer but the pathologic examination showed in the sections of the ulcer "evident induration which was the result of dense overgrowth of connective tissue, everywhere diffusely, and near the surface focally, infiltrated with leukocytes. There was no evidence of epithelial infiltration, and the gastric mucosa on each side of the ulcerated area appeared normal. The lymph

24	70	♀	Palpitation 2 years
25	45	♀	Vomiting and distress 1 year
26	59	♂	Sore spot in stomach 20 years
27	58	♀	Cholecystectomy 5 to 6 years ago; pain not relieved
28	69	♂	Dyspepsia 20 years
29	68	♀	Weakness past several years
31	73	♂	Vomiting, pain, loss of weight 4 months
32	60	♀	Weakness, loss of weight, 6 months
33	53	♂	Weakness 18 months
34	52	♂	Pain and weakness 4 years
36	74	♂	Abdominal pain 30 years
37	73	♂	Ulcer pain 13 years
38	55	♀	Weakness, loss of weight, 1 year

gland told another story; despite its small size it showed the presence of numerous masses of undelimited epithelial cells, in part with a fairly definite tubular arrangement, in part as utterly unformed groups. Despite the negative evidence of the sections directly through the ulcer there was undoubtedly carcinomatous change somewhere in the ulcer." This patient is still living at the age of 70 and still carrying on his work as an educator. His stomach, as that of the previous patient, showed considerable deformity at the pyloric region on x-ray examination one year ago, but it is functioning sufficiently well to carry on approximately normal gastric digestion.

The point brought out by the three cases I have cited is that even with the abdomen open and the stomach accessible to sight and feel it is extremely difficult to differentiate between benign gastric ulcer and early carcinoma. For this reason I advocate the removal of prepyloric ulcer, in whatever portion of the stomach it is situated, by the method applicable to the individual case with or without gastric drainage by gastro-enterostomy. In the early stage, with the patient in good condition, the operation does not carry a high mortality and removal of the ulcer and the surrounding area is radicalism on the side of safety.

CONCLUSIONS

The development of surgery initiated by the discovery of anesthesia and asepsis has passed through two definite phases and we should now be entering on its third phase.

The first phase was that of anatomic surgery. The attention of surgeons was directed toward developing methods of attack on the different organs of the body. During this phase the various operations were devised and surgical thought was directed almost exclusively to anatomic and mechanical methods.

The second phase was ushered in by the increase in the knowledge of bacteriology and biochemistry. The condition of the patient's body was more carefully evaluated, and preoperative and postoperative care of the patient as a whole was taken into consideration. The physiology of the different organs of the body was studied and surgical attack directed toward conditions which were previously out of reach because of the inability of the unprepared patient to stand the shock of surgical attack.

The third phase, into which we are now entering, is the phase of preventive surgery. The great mass of evidence accumulated over the past three quarters of a century has shown definite conditions amenable to surgical attack which we know, if left alone, will result in serious disability, if not death, in a moderately short time. In this group can be placed thyroid disease, which tends constantly to become more and more severe. Gallbladder disease, which tends to create economic inefficiency in later life, also may be included. The wisdom of surgical removal of the various so-called precancerous conditions is now recognized. It would appear from the evidence offered by this study, as well as by that offered by others, that gastric ulcer belongs to this group if we are to succeed in the surgical cure of cancer of the stomach.

Cancer of the stomach sufficiently advanced that a definite diagnosis of cancer can be made is, as shown by this series and series reported by others, a condition which is practically incurable by surgical treatment. Recurrences are common. In many cases metastases exist which cannot be recognized at operation. At best, in the advanced case, operation gives the patient only a few more months of life. In the majority of cases life is made more comfortable and consequently operation is justified.

The accepted method of cure, if the word can be used of carcinoma of any form, is the early removal of the growth itself with the removal of adjacent lymph glands. From the standpoint of the surgeon the treatment of carcinoma of the stomach consists in the removal of gastric lesions which we know may result in carcinoma during the stage when, if carcinoma is already present, it is in an early stage and localized in the stomach and adjacent glands.

1618 Medical Arts Building.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
HOWARD A. CARTER, Secretary.

HARRIS OXYGEN REGULATORS, No. 92SC ACCEPTABLE

Manufacturer: The Harris Calorific Company, 5505 Cass Avenue N.W., Cleveland.

The Harris Oxygen Regulator, No. 92SC, is used to meter the flow of oxygen into tents, catheters, anesthesia apparatus or similar oxygen therapy chambers. It is a two-stage regulator, which is designed, in contradistinction to single-stage regulators, to reduce pressure in two steps.

Harris Oxygen Regulators
#92SC.

The firm claims that this type of apparatus is more efficient than a single-stage regulator, in which the high pressures encountered in the oxygen cylinders are both held and controlled at one point, namely where the nozzle meets the seat. It is stated that this dual function cannot be efficiently maintained by one such control. That is, in the two-stage mechanism a more steady and rigid means may be provided to "hold" the pressure by means of a separate first stage, and a more

accurate and stable control is made possible by the presence of a second stage. The first is achieved by a metallic diaphragm set to hold the pressures roughly at from 150 to 200 pounds. Gas at this pressure is then led into the second stage, where a flexible diaphragm functions in connection with a seat to regulate the gas more accurately. Furthermore, it is said that this second stage diaphragm is so made that no harm would ensue if a nurse should inadvertently leave the second stage seat open and then open the valve on the oxygen cylinder, allowing 2,000 pounds of gas pressure to rush directly onto the more delicate second stage diaphragm.

In this unit there is also a screen through which gas entering the regulator is subjected to filtering prior to entering the high pressure gage and the seat. A safety valve has been provided to vent to the atmosphere undesirably high gas pressures. The noise of the operation of the unit has also been reduced to a minimum.

The firm submitted tests made in its engineering department to substantiate claims that the regulator will hold and accurately control 2,000 down to 100 pounds pressure. The delivery per minute was set at 20, and the results were as follows:

Oxygen Cylinder Pressure Lbs. per Sq. In.	Delivery Liters per Minute
2,000.	10
1,800	10
1,600	9.9
1,400	9.8
1,200	9.7
1,000	9.6
800	9.5
600	9.4
400	9.5
300	9.7
200	10.1
150	10.5
100	10.8

Evidence obtained by the Council for the clinical value of the unit demonstrated that it performed adequately and in accordance with the claims of the firm.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Harris Oxygen Regulators, No. 92SC, for inclusion on the Council's list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

BISMUTH ETHYL CAMPHORATE (UPJOHN COMPANY)

Preliminary Report of the Council on Pharmacy and Chemistry

The Upjohn Company presented for the Council's consideration, Bismuth Ethyl Camphorate, stated to be a liposoluble bismuth salt of ethyl camphoric acid having the formula $(C_8H_{11}COOC_2H_5COO)_2Bi$. The preparation is proposed for intramuscular injection to obtain the systemic effects of bismuth in the treatment of syphilis. The proposed adult dose is 1 cc. by intramuscular injection for a course of twelve injections. The firm states that the drug is usually administered in courses alternating with arsenic preparations. It is marketed in ampules of 1 cc. and vials of 30 cc., each cubic centimeter containing 40 mg. of elemental bismuth, 0.010 Gm. of camphor and 0.025 cc. of benzyl alcohol dissolved in sweet almond oil. These dosage forms have not been checked by the Chemical Laboratory of the American Medical Association.

The Upjohn Company submitted evidence to show that the minimum lethal dose for the bismuth-methyl-camphorate was 350 mg. of metallic bismuth per kilogram of rat, while that for bismuth-ethyl-camphorate was 250 mg. of metallic bismuth per kilogram of rat.

The firm submitted a reprint entitled "Bismuth Ethyl Camphorate, clinical observations on a new oil soluble bismuth in the treatment of syphilis," by Francis M. Thurmon representing work done in the Department of Dermatology and Syphilology and the Division of Research of the Boston Dispensary. The statement is made that oil soluble preparations possess an optimum rate of absorption and elimination and a superior ability to penetrate the tissues. No proof for this statement is given. Investigation included 230 patients who received 2,444 intramuscular injections, extending over a period of eighteen months. There were nineteen patients with primary lesions, thirty-six with secondary, ninety-one with tertiary asymptomatic, sixty-three with tertiary symptomatic, and twenty-one with congenital syphilis. There were 146 males and eighty-four females (of the latter fourteen were pregnant). Each patient had frequent chemical and microscopic studies of the urine. Occasionally phenolsulfonphthalein excretion tests were used, and determinations of the nonprotein nitrogen and urea content of the blood were carried out. Likewise, complete blood counts, icteric index and like tests were made in numerous instances. In these tests no significant variations from normal were observed which might be attributed to Bismuth Ethyl Camphorate. It was found that the patients best tolerated the 1 cc. dose of the compound given intramuscularly. Higher doses of 1.5 cc. and 2 cc. were well tolerated by some patients, while others manifested local pain, gingivitis, occasionally a mild dermatitis, and seldom evidence of a transient renal irritation.

The technic employed in the foregoing clinical study consisted, in early syphilis, in each patient receiving three injections of an arsphenamine for the first two weeks, two injections a week for the next two weeks and one injection a week for the succeeding two weeks, so that at the end of the first six weeks of treatment each patient had received twelve intravenous injections. Then without a rest period intramuscular therapy was instituted, the patients receiving an injection of bismuth ethyl camphorate at seven day intervals for a total of twelve injections. Following this the patient was once more put back on the arsenical therapy, and this continuous alternation of courses was kept up until the patient had received thirty-six injections each of an arsenical and of a bismuth preparation. The seventy-two injections were considered the minimum therapy for any patient with primary or secondary syphilis.

The author states that occasionally prolonged treatment with bismuth ethyl camphorate was necessary because of sensitivity to other preparations, so that twenty-one patients received from fifteen to twenty consecutive injections, and another group of

fifteen patients received from twenty to twenty-five injections without toxic effect. One patient, a man aged 20, sensitive to all arsenicals, developed an acute interstitial keratitis, for which he received twenty-nine consecutive injections without toxic effect and with a clearing of the eye situation in six weeks. In fourteen cases of pregnancy, five of them in the secondary stage in which it was possible to administer treatment through the last five months of pregnancy, each of the patients produced a full-term child without stigmas of congenital syphilis.

The firm submitted a table comparing the toxic effects of bismuth ethyl camphorate with that of bismuth subsalicylate. According to this table, if anything, more toxic effects were noted from bismuth subsalicylate than from bismuth ethyl camphorate, there being a comparison of 230 cases under the bismuth ethyl camphorate, with 180 under the bismuth subsalicylate. As to local irritation from the preparation, in only eight instances of the 230 was it necessary to transfer the patient to some other form of treatment. It is stated that during the early period of the study when larger amounts of the drug, from 60 to 80 mg., were used, the drug seemed to possess potential possibilities of toxicity. Later and more complete evidence would indicate that Bismuth Ethyl Camphorate can be used in 2 cc. (80 mg.) doses, as are other liposoluble compounds on the market, though one consultant reports that some of the patients under such a regimen develop a bismuth line within a matter of two or three weeks. Otherwise there seems to be no reason why a 2 cc. dose should not be considered safe.

No studies were submitted on the absorption and elimination of this product. Evidence is presented to show that it is impossible by means of x-ray examination to study the rapidity of absorption of Bismuth Ethyl Camphorate when administered intramuscularly. The x-ray films show no evidence of any opaque material.

The Upjohn Company was informed that the Council has already gone on record as being opposed to development of further bismuth preparations for the treatment of syphilis unless they represent something new and of an unusual type. Bismuth ethyl camphorate can hardly be called a new or unusual type of preparation. Sufficient data are not furnished to allow proper evaluation of the effectiveness of this product in the treatment of syphilis. Studies on the absorption and elimination of the preparation in human subjects are lacking. Some data are furnished on animals. It is understood that the investigation of the former is in progress. For one of the first requisites to evaluation of an antisiphilitic preparation, the rapidity of disappearance of spirochetes from primary and secondary lesions, insufficient data are at hand. Thus far they consist of but one case of Dr. Carroll Wright's, in which the spirochetes disappeared from a penile chancre in approximately sixty hours, and eight cases submitted by Dr. Francis Thurmon, the spirochetes disappearing from the primary lesions in one, two and three days respectively, and from secondary lesions, several of them being extensive condylomas, in extremes of two and fourteen days, with a mean of thirteen days. In view of the lack of sufficient data to warrant inclusion in N. N. R. at this time, the Council authorized publication of the foregoing preliminary report.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

SULFANILAMIDE (See New and Nonofficial Remedies, 1939, p. 463).

Tablets Sulfanilamide, 5 grains.

Prepared by Smith-Dorsey Co., Inc., Lincoln, Neb. No U. S. patent or trademark.

IMMUNE GLOBULIN (HUMAN) (See New and Nonofficial Remedies, 1939, p. 412; THE JOURNAL, April 1, 1939, p. 1257).

The National Drug Co., Philadelphia.

Immune Globulin (Human).—Also marketed in packages of one 2 cc. ampule-vial and in packages of one 10 cc. ampule-vial.

SATURDAY, OCTOBER 21, 1939

HEAD INJURIES

In recent years two dominant influences have prevailed in the treatment of trauma to the brain. The first is the demonstration of the four classic stages of brain compression by Kocher and Cushing. The second is the observation of Weed and his collaborators that increased intracranial tension can be influenced by changing the osmotic pressure of the blood through the agency of hypertonic and hypotonic solutions. The treatment of cerebral injuries has been designed also on the concept that cerebral compression is the prime factor in the production of the symptoms. The application has resulted in treatment by cerebral decompression—by lumbar puncture and by dehydration. Thus Battle,¹ after a recent study of 200 cases of traumatic injuries of the head, has reported that the lowest mortality in the seriously injured occurred in the cases treated by repeated lumbar punctures and dehydration.

Now, however, comes evidence that the postulates on which therapy has rested are neither wholly complete nor wholly accurate. Shapiro and Jackson,² for example, in studies of normal human brains and those which had suffered traumatic injury, found that in the traumatized head the brain is swollen but not edematous. This swelling is not due to increased water but to increased blood content, although the ventricular fluid is increased in the presence of internal traumatic hydrocephalus. The lines of therapeutic effort suggested by their study show, these investigators believe, that lumbar puncture and dehydration are indeed indicated but have probably been carried as far as possible. Ventricular drainage may be useful but emphasis may be placed on measures to reduce parenchymatous hemorrhage within the brain substance. Similarly, Browder and Meyers³ have previously expressed inability to interpret clinically the altered brain functions of many traumatic cases in

terms of the classic teachings. This led to their investigation of the behavior of the blood pressure, pulse, respiration, state of consciousness and cerebrospinal fluid pressure following craniocerebral injury. Measurably increased intracranial tension rarely, however, produced the classic pattern of signs; they therefore expressed the conviction that, whether singly or in combination, the blood pressure, pulse rate, respiratory rate and state of consciousness cannot be reliably regarded as an index of intracranial tension. Three lines of evidence concerning the factor of cerebral compression—that derived from observations on the behavior of the systemic blood pressure, pulse and spinal fluid pressure following craniocerebral injury; that from alterations in vital signs associated with changes in intracranial tension experimentally produced by an external pressure agent, and that from the alterations in vital signs associated with changes in intracranial tension experimentally produced by the application of an intraventricular pressure agent—lend strong support to the view that the changes in the constitutional, neurologic and psychologic states of patients showing evidence of severe trauma of the brain are not applicable in terms of increased intracranial tension per se.

Their extensive experiments on this problem⁴ involved also observations on the effects of various hypertonic solutions on the intracranial tension as measured by the cerebrospinal fluid pressure and aerographic roentgenologic studies of the head in relatively new injuries demanding prompt and precise diagnosis as a basis for therapy. All these observations point to the conclusion that the traditional account of the manifestations of craniocerebral trauma in terms of brain compression cannot be reconciled in the majority of cases with the data derived from clinical, pathologic and experimental investigations. The evidence available rather indicates the necessity of experimental inquiry into the nature of the more subtle pathologic intracerebral disturbances, particularly of the derangements of the physiochemical constitution of nerve cells and their processes. Until precise knowledge along such lines is acquired, Browder and Meyers say, bringing with it an understanding of the pathogenesis of the majority of severe cerebral injuries comparable to that at present possessed in connection with epidural, subdural and intracerebral hemorrhages, just so long will treatment remain empiric. The proper management of a head injury, they say, requires the clinician to determine whether or not there are present any lesions such as depressed fractures of the vault and epidural, subdural or intracerebral hematomas. These alone are benefited by surgical procedures. Other pathologic processes call for the institution of supportive measures. Differential diagnosis is often rendered difficult by the frequent coexistence of generalized cerebral insult with

surgically amenable conditions. In such cases cerebral aerography may help to clarify the diagnosis. Certainly the severe traumatic head injuries still constitute a sufficiently dangerous group to necessitate extensive further studies on the pathophysiology in order to furnish a foundation on which to base more rational and effective therapy than is at present available.

POTASSIUM IN MUSCLE

The concentration of the electrolytes in the various tissues of the body is maintained by a variety of intricate mechanisms, not all of which are well understood. The electrolytes of muscle, in particular, have attracted much attention; the extensive literature covering research studies made in this field was recently reviewed by Fenn.¹ The important observations of numerous investigators which give evidence that under certain conditions muscles lose potassium on stimulation have made studies concerning this element of special interest. A recent investigation by Heppel,² who used potassium deficient rations, is noteworthy because it adds to our knowledge of the interrelations of potassium and sodium in muscle. Restriction of rats to such an experimental diet results in a striking alteration in the potassium and sodium content of their muscular tissues. As compared to normal animals, those deprived of potassium show a decrease of almost 50 per cent in the potassium of muscle and a concomitant rise in the level of sodium; indeed, in some cases the muscles become richer in sodium than in potassium. Particularly worthy of note is the observation that in the muscles of the deficient animals most of the sodium is confined to the intracellular phase, whereas it is known that in the muscles of normal rats almost all the muscle sodium can be assigned to the extracellular space. It might be recalled here that Eppright and Smith,³ in a study of the changes in the water of tissue induced by diets containing various mineral supplements, also reported the probable occurrence of intracellular sodium in the muscles of rats under a particular dietary regimen.

Although the livers of rats deprived of potassium examined by Heppel showed no large changes in the electrolyte picture, the possible importance of the liver in the potassium economy of the body is suggested by the recent work of Fenn.⁴ He has reported the results of an extensive study which was carried out to determine the fate of potassium liberated from muscles during activity. His observations indicate that the liver is involved in a manner not suspected heretofore. The blood, muscles and other tissues of cats were analyzed for water and potassium before and after stimulation

of certain muscles. The data show that one hour after stimulation the increase in potassium concentration in the blood is such as to indicate that more than half of this element is no longer located in the interstitial or circulatory fluids but must have penetrated into some cells of the body. Analysis of the liver indicates that this organ takes up 31 per cent of the potassium liberated from active muscles, although it accounts for less than 3 per cent of the body water.

The experiments would seem to indicate that a part of the potassium liberated by muscular activity is taken up by the liver; in recovery the reverse change occurs, since it has been shown that the muscle regains the potassium which it has lost. Thus there are indications of a potassium cycle that is somewhat comparable to the classic carbohydrate cycle, the potassium being possibly transported as potassium lactate. As recognized by Fenn, additional evidence is needed before the existence of such a cycle can be stressed. However, if further work proves that this cycle exists, the importance of the discovery to our knowledge of tissue electrolytes is evident. The involvement of the liver in the cycle would also serve to emphasize once more the manifold function of this organ in metabolism.

HEMOCONCENTRATION AS A DIAGNOSTIC SIGN OF SHOCK

Observations on shock during the World War seemed to show that substances absorbed from injured tissues were responsible for the circulatory failure which followed. The British Medical Research Council organized an investigation on the nature and appropriate treatment of shock. Eminent surgeons, physiologists and pharmacologists of England, France and the United States cooperated in this endeavor. The accumulated experience and experimental evidence, summarized by Cannon, indicated that secondary shock is due to a toxic factor absorbed from injured tissues which causes an increase in permeability of the capillary walls and a consequent reduction in blood volume through the escape of plasma into the tissues. In a large series of cases of hemorrhage and of shock in which hemorrhage was insignificant, Cannon, Fraser and Hooper¹ found that the blood showed dilution in the former proportional to the amount of blood lost, while in the latter there was concentration of the blood. The first noteworthy feature in severe traumatic shock was a high red cell count. These investigators attributed this phenomenon to stasis of blood in capillary areas, accompanied by transudation of the plasma into the tissue spaces, with resulting concentration of the corpuscular elements of the blood. The hemoconcentration was progressive and tended to be proportional to the degree of shock.

1. Cannon, W. B.; Fraser, John, and Hooper, A. N.: *Some Alterations in the Distribution and Character of the Blood*, *J. A. M. A.* **70**: 526 (Feb. 23) 1918.

Knowledge concerning the function and reactions of the capillaries has been extended since the World War. It has been shown (Ebbecke,² Lewis³) that normal cytoplasmic substance, released from cells by injury of any kind, causes dilatation and increased permeability of capillary endothelium. Cytoplasm is not toxic in the sense commonly implied by that term. According to Moon,⁴ secondary shock is the result of capillary atony caused by many agents, such as cytoplasmic substances, anoxia, certain chemicals, metabolites and various protein substances. The phenomena which accompany capillary atony are hemoconcentration, dilatation, stasis and permeability of capillary endothelium. These result in a decrease in both the actual and the effective blood volume. The volume flow is thereby reduced and deficient delivery of oxygen causes tissue anoxia. Capillary dilatation combined with loss of plasma volume causes disparity between the volume of blood and the volume capacity of the vascular system. For a time arterial constriction will compensate this disparity. This compensation is at the expense of volume flow. The peripheral parts become relatively bloodless and vital organs suffer lack of oxygen. When this mechanism of compensation is no longer effective, the blood pressure declines progressively. At this stage the condition is usually irreversible.

Moon and his associates claim that shock is accompanied regularly by hemoconcentration, and they have adopted hemoconcentration as a criterion rather than changes in blood pressure. They produced shock in dogs without hemorrhage or trauma by introducing muscle substance intraperitoneally, by injecting extracts of tissue, by injecting bile and by other procedures. Hemoconcentration was a regular feature in all the experiments, sometimes developing within an hour after implantation of muscle. It occurred before the arterial blood pressure began to decline and was progressive. The degree of concentration was proportional to the apparent illness of the animal. A condition of collapse, relaxation and stupor preceded death.

Moon and his associates found that hemoconcentration develops gradually after severe trauma, operations, intestinal obstructions and burns but that it results immediately after the injection of bile, peptone, histamine, emetine and other substances which cause damage to endothelium. A rise from 5,000,000 to 6,000,000 red cells represents a concentration of 20 per cent. Such a result, according to Moon, indicates that the total blood volume has been reduced about 10 per cent and the plasma volume about 20 per cent. A hemoconcentration of 20 per cent is ominous, for it indicates that the mechanism of shock is in operation even though no decline in arterial pressure or other evidence of circulatory deficiency is shown.

Moon⁵ points out that hemorrhage and shock may be differentiated readily by observations made on the concentration of the blood. A loss of blood by hemorrhage results in dilution of the blood because fluid is absorbed rapidly from the tissues to restore the blood to its normal volume. The hemodilution is proportional to the amount of blood lost. Moon compared the hemoconcentration with blood pressure readings in a number of clinical cases during the development of circulatory deficiencies of the shock type. In each instance, examination of the blood forecast the development of the shock from several hours to several days before the blood pressure declined notably. He therefore concluded that arterial blood pressure is not an accurate criterion of the presence of shock. The latter may be present while the blood pressure is well maintained or when it is even at its highest recorded point. Hemoconcentration is progressive; it is an index of the degree of shock, and it subsides to normal as shock is abated. Hemoconcentration is therefore offered as the earliest clinical sign of shock. It is easily detected, is regularly present before other signs appear and results from the same mechanism that causes shock.

Current Comment

MASSACHUSETTS COMES CLEAN

At long last the Commonwealth of Massachusetts has taken measures for the protection of its citizens in medical affairs comparable to those of other states. For years the output of graduates of low grade medical schools unable to obtain licenses in any other state has flocked to Massachusetts. Two such schools not recognized in any other state have flourished almost under the shadow of the State House. In theory people were protected by the licensing examination; it is well known, however, that competence to practice medicine cannot be determined by a written examination alone. A written examination might as well be expected to test ability to paint a picture or to shoe a horse. The state has provided no machinery for a practical examination, which is the only kind of examination worth while in ascertaining fitness for medical practice. Now, however, by the Acts of April 30, 1936, and May 2, 1938, amending section two of chapter 112 of the General Laws, it has been decreed that no one may enter the licensing examination who is not a graduate of an "approved" medical school. There has also been created an "Approving Authority" which is to determine on request whether any medical school fulfils the requirements formulated and published by it. The way is now clear to enforce a standard for admission to the practice of medicine at least as high as the standards prevailing generally throughout the United States. After 1941 Massachusetts should cease to be the dumping ground of unqualified practitioners.

SUPPLY OF OPIUM IN THE
UNITED STATES

According to official reports, opium and its derivatives are now available in the United States in quantities sufficient to meet legitimate medicinal requirements for about three years. Disturbed conditions in Europe and the Orient afford, therefore, no justification for purchasing and hoarding supplies of these drugs, either by physicians, hospitals, wholesale druggists or pharmacists. Narcotic peddlers, however, who cater unlawfully to addicts, seem to feel already the pinch of restricted transoceanic commerce. The importation of opium and its derivatives by international smugglers apparently has diminished along with the number of vessels engaged in transoceanic commerce. The increasing difficulty of obtaining narcotics to satisfy the demands of addicts probably accounts for the increase in the number of thefts of narcotics from physicians' offices and from pharmacies. Addicts and peddlers who cater to them are likely to resort with increasing frequency to this method of replenishing their stocks. Physicians, pharmacists and institutions who may legitimately possess narcotic drugs should take extra precautions to prevent their being stolen. Access to such drugs should be limited to the smallest possible number of persons. In event of theft of narcotics, the person from whom they were stolen should make immediate report in writing to the local police and also to the narcotic agent in charge of the district in which the theft occurs. Such reports are necessary for physicians in presenting a correct inventory of their narcotic supplies when called on to do so.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Annual Symposium on Heart Disease.—The tenth annual postgraduate symposium on heart disease, given by the heart committee of the San Francisco County Medical Society, will be held at the University of California Hospital, Stanford University Hospital and San Francisco Hospital, San Francisco, November 16-18. The course will include demonstration of patients, ward rounds and special instruction in roentgen examination and electrocardiography. At the dinner meeting the opening night Dr. William Dock, professor of pathology at Stanford, will speak on "The Treatment of Heart Disease Since Queen Bess."

Resolutions of an American Legion Post.—Service Clubs Post No. 546 of the American Legion of the Department of California, at Los Angeles, comprising mostly men of executive rank in their own organizations who are former officers in the military service, has unanimously adopted two resolutions. In the first resolution, the post stated that military mobilization would require thousands of doctors and, since only about 20 per cent of those applying for admission to medical schools at present are admitted, in selecting students for admission to medical schools adaptability for military service should be considered along with the other requirements; that R. O. T. C. graduates be given preference if otherwise equally qualified; also that the number of admissions to medical schools annually should be increased to provide enough doctors of medicine to serve the military forces in time of war and leave a surplus sufficient to serve the needs of the civilian population. The other resolution adopted by the post provided that further to improve the medical department of the U. S. Army

and Navy a study be made to determine the feasibility of requiring all applicants for admission to the dental corps to be doctors of medicine specializing in dentistry. This resolution pointed out that at present in the medical department of the U. S. Army and Navy there are about 400 officers of the dental corps whose professional training is along the lines of medical officers but whose effectiveness is limited almost entirely to their technical ability.

COLORADO

Annual Session.—The Colorado State Medical Society will hold its annual session in Glenwood Springs Sept. 11-14, 1940, with headquarters at the Hotel Colorado.

Society News.—Dr. John Alexander, Ann Arbor, Mich., discussed "Surgery of Bronchiectasis and Abscess of the Lung" before the Medical Society of the City and County of Denver October 3. Dr. Elliott P. Joslin, Boston, addressed the society September 3 on "Treatment of Diabetes—1898-1939."—The Pueblo County Medical Society was addressed September 19 by Dr. Arthur J. Markley, Denver, on "Basic Factors of the Syphilis Control Program." Dr. Paul S. Wolfe addressed the society recently on craniocerebral injuries.

CONNECTICUT

Changes in Health Officers.—The *Connecticut Health Bulletin* announces the following changes in health officers: Dr. Homer C. Ashley, New Hartford, of Barkhamsted, filling the vacancy caused by the resignation of Marshall Case; Dr. Norman H. Gardner, East Hampton, succeeding Dr. John D. Milburn, resigned; Dr. Howard S. Allen of Woodbury, succeeding Dr. Frank Reichenbach, and Dr. William L. Higgins, South Coventry, of Columbia.—Dr. Daniel E. Shea, formerly director of the bureau of venereal diseases of the Hartford department of health on a part time basis, has been appointed full time director.

Society News.—The Yale Medical Society was addressed in New Haven October 11 by Walter R. Miles, Ph.D., on "The Polarity Potential of the Human Eye"; Dr. Robert M. Thomas and Frederick Dessau, "Experimental Tuberculosis in Mice"; Bert G. Anderson, D.D.S., "Developmental Enamel Defects; Clinical Descriptions and Classification," and Robert M. Lewis, "Use of a Synthetic Preparation Replacing Estrin."—Dr. Milton C. Winternitz, New Haven, addressed the Fairfield County Medical Association in Greenwich October 17 on "Infecting Agencies and Pathology."—At a joint meeting of the Hartford Medical Society and the Hartford County Medical Association October 16 Dr. Foster Kennedy, New York, discussed "Emotional Unrest in a Restless World."

ILLINOIS

New District Health Units.—The state department of health announces the establishment of four new district health units. There are now nineteen of these units offering full time service to ninety-six of the 102 counties in the state. The medical officers in charge of the new units are Drs. Abraham J. Levy, Gilman; Cecil A. Z. Sharp, Macomb; Clair L. Jolins, Mount Sterling, and Jerome J. Sievers, Pana.

Symposium for Industrial Nurses.—The first annual symposium for industrial nurses will be presented by the state department of public health at the University of Illinois College of Medicine, Chicago, October 26-28. Collaborating organizations are Chicago Industrial Nurses Association, Greater Chicago Safety Council, Illinois Manufacturers Association, American Industrial Hygiene Association, American Medical Association and the University of Illinois College of Medicine.

Society News.—At a meeting of the Adams County Medical Society in Quincy September 11 Dr. Nathan S. Davis III, Chicago, spoke on "The Care of the Aged."—Dr. Carolyn N. MacDonald, Chicago, addressed a public meeting in Charleston September 28 on "The Importance of Prenatal Care"; the meeting was sponsored by the Coles-Cumberland County Medical Society and the Charleston Woman's Club.—At a meeting of the Rock Island County Medical Society in Rock Island September 26 Dr. Abraham F. Lash, Chicago, discussed "Prevention and Treatment of Abortion."—Dr. Archibald L. Hoyne, Chicago, discussed scarlet fever before the Kankakee County Medical Society at Kankakee September 14.—At a meeting of the Bureau County Medical Society September 12 in Princeton Dr. Roger T. Vaughan, Chicago, discussed "Differential Diagnosis and Treatment of Acute Abdominal Lesions."—Dr. William J. Morginson, Springfield, addressed the Christian County Medical Society, September 6, on "Diagnosis and Treatment of Some Common Skin Diseases."

Chicago

The Belfield Lecture.—Dr. Samuel R. Meaker, professor of gynecology, Boston University School of Medicine, will deliver the eleventh annual William T. Belfield Memorial Lecture of the Chicago Urological Society at the Palmer House October 26. His subject will be "Male Infertility from a Gynecologic Viewpoint."

Society News.—At a meeting of the Chicago Pathologic Society October 9 the speakers were, among others, Dr. Samuel A. Levinson, who delivered the presidential address on "History and Progress of the Scientific Work of the Cook County Coroner's Office" and Dr. Edith L. Potter, "Disseminated Ganglioneuroblastoma in a Stillborn Fetus."—Dr. Walter C. Alvarez, Rochester, Minn., addressed the Chicago Society of Allergy October 16 on "Gastrointestinal Allergy" and Dr. Charles K. Maytum, Rochester, Minn., spoke on "Oxygen Therapy and X-Ray Therapy in Asthma."—At a meeting of the Chicago Pediatric Society October 17 Drs. Arthur F. Abt and Heyworth N. Sanford spoke on "Hemolytic Disease in Infants" and "Nuclear Icterus" respectively.—The Chicago Gynecological Society was addressed October 20, among others, by Drs. Eustace L. Benjamin and William C. Danforth, Evanston, Ill., on "Bipartite Uterus" and Robert M. Grier and Herbert O. Lussky, Evanston, Ill., "Premature Infant Mortality."

INDIANA

Memorial to Physician.—A memorial to the late Dr. St. Clair Darden, South Bend, superintendent of Healthwin Hospital from 1920 to 1932, was unveiled recently. The monument is a large granite boulder, bearing a bronze plaque, given by persons who attended Camp Darden. Dr. Darden died Nov. 15, 1932.

Marihuana Eradication.—A program of eradication of marihuana and education of the public to the dangers of the weed has been launched in Indiana by Dr. Verne K. Harvey, secretary, state board of health, in compliance with a recent law. Gene Ryan, Indianapolis, formerly a state police detective, has been appointed state narcotic inspector in charge of marihuana eradication and enforcement.

MASSACHUSETTS

Society News.—Gregory Pincus, Sc.D., visiting professor of experimental zoology, Clark University, Worcester, discussed "Sex Hormones in Cancer" before the Worcester District Medical Society in Worcester September 13.—At a meeting of the Pentucket Association of Physicians September 14 in Haverhill, Dr. William Dameshek, Boston, spoke on "Lessons from the Blood Applicable to Problems of the General Practitioner."

The New England Postgraduate Assembly.—The New England Postgraduate Assembly, sponsored by the state medical societies of Massachusetts, New Hampshire, Rhode Island, Maine and Vermont, will be held at the Sanders Theater, Harvard University, Cambridge, October 31–November 1. Lecturers will include:

Dr. Jesse G. M. Bullock, New York, Basis of Specific Therapy in the Management of the Pneumonias.
Dr. Roscoe R. Graham, Toronto, Ont., Canada, Chronic Cholecystitis.
Dr. Albert C. Furstenberg, Ann Arbor, Mich., Acute Suppurations of the Mouth and Pharynx.
Dr. James S. McLester, Birmingham, Ala., The Role of the Vitamins and Other Essential Substances in Human Nutrition.
Mr. H. H. Clegg, federal bureau of investigation, U. S. Department of Justice, Washington, D. C., The War on Crime.
Dr. Benjamin W. Carey, Detroit, Pyelitis in Children.
Dr. Eldridge L. Eliason, Philadelphia, Team Work in the Treatment of Gallbladder Disease.
Dr. Joseph E. Moore, Baltimore, Latent Syphilis.
Dr. Harvey B. Matthews, Brooklyn, Pelvic Infection: Diagnosis and Management.
Dr. Maurice C. Pincoffs, Baltimore, Clinical Varieties of Hypertension.
Dr. Charles C. Higgins, Cleveland, Prevention of Recurrent Renal Lithiasis.
Sir Thomas Lewis, Rickmansworth, England, Venous Congestion and Its Measurement.

MICHIGAN

State Medical Election.—Dr. Paul R. Urmston, Bay City, was chosen president-elect of the Michigan State Medical Society at its recent annual session and Dr. Burton R. Corbus, Grand Rapids, was installed as president.

Goiter Prevention.—A statewide educational program to promote the use of iodized salt as a preventive of simple goiter is being sponsored this month by the state department of health, the state medical society and the Salt Producers Association of Michigan. The work will be carried on prin-

cipally through the schools. Physicians, health officers and nurses who wish copies of the folder "Michigan Children Need Iodized Salt" for distribution may obtain them from the state department of health, Lansing.

The Max Ballin Lectures.—The North End Clinic, Detroit, announces the Dr. Max Ballin Memorial Lectures to be given at the Detroit Institute of Art. The following speakers will discuss "Newer Applications of Practical Surgical Physiology" as applied to the listed topics:

Dr. Isidore S. Raydin, Philadelphia, Gallbladder and Biliary Tract, November 1.
Dr. Charles F. Geschickter, Baltimore, The Breast, November 8.
Dr. Edward William Alton Ochsner, New Orleans, Preoperative and Postoperative Care, November 15.

New Virus Research Center.—The National Foundation for Infantile Paralysis has awarded an annual grant of \$12,900 to the laboratories of the state department of health to establish in Lansing a virus research laboratory. A special grant of \$5,000 has been given by the U. S. Public Health Service to aid in providing necessary laboratory facilities where this research work may be carried on. Dr. Sidney D. Kramer, formerly of Brooklyn, executive secretary, general advisory committee, National Foundation for Infantile Paralysis, has been appointed director of the state department's new division of virology, which will supervise the new laboratory. Dr. Henry E. Cope, Detroit, has been appointed to the staff of the bureau of laboratories to take charge of the division of clinical pathology. He will be associated with Dr. Kramer it is reported.

MISSOURI

Jackson County Health Forum.—Announcement is made of the 1939–1940 season of the Jackson County Health Forum, sponsored by the auxiliaries of the accredited hospitals of Jackson County. The preliminary notice lists the following speakers:

Dr. Louis J. Karnosh, Cleveland, September 20, Medicine and Crime.
Dr. Rock Sleyster, Wauwatosa, Wis., President of the American Medical Association, October 18, What Price Depression?
Dr. Philip Lewin, Chicago, November 15, Your Feet Deserve Good Care.
Dr. Thurman B. Rice, Indianapolis, December 20, Mental and Emotional Hygiene.
Franklin C. Bing, Ph.D., Secretary, Council on Foods, American Medical Association, January 17, Vitamin Follies.
Dr. Henry F. Helmholtz, Rochester, Minn., February 21, How to Avoid and Care for the Diseases of Infancy and Childhood.
Dr. Elliott P. Joslin, Boston, March 20, Diabetes.
Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, April 17, Frontiers of Medicine.

NEBRASKA

Annual Clinical Assembly in Omaha.—The seventh annual assembly of the Omaha Mid-West Clinical Society will be held October 23–27 with headquarters at the Hotel Paxton. There will be general assemblies each morning; clinics will be held each afternoon and scientific sessions each evening. The guest speakers will be:

Dr. Clarence Rutherford O'Crowley, Newark, N. J., Anomalies of Kidney and Ureter; Polycystic Kidney Disease.
Dr. Charles Anderson Aldrich, Winnetka, Ill., Treatment of Nephritis in Childhood; Role of Gratification in Early Development.
Dr. Clifford J. Barborka, Chicago, Subclinical States of Nutritional Deficiency; Medical Management of Gallbladder Disease.
Dr. Walter Schiller, Chicago, Diagnosis of Malignancies of the Female Generative Tract; Sexual Abnormalities in Females.
Dr. William Wayne Babcock, Philadelphia, Intestinal Malignancy; Clinical Methods as a Guide to the Diagnosis and Treatment of Various Surgical Affections.
Dr. Frank E. Burch, St. Paul, Ocular Evidences of Intracranial Disease; Recent Advances in Ophthalmic Therapeutics.
Dr. Louis J. Karnosh, Cleveland, Diagnosis and Treatment of Polyneuritis; Recognition and Management of Early Psychiatric Problems in General Practice.
Dr. Grandison D. Royston, St. Louis, Recognition and Treatment of Pelvic Malignancy; Indications and Contraindications for Operative Delivery.
Dr. James S. Speed, Memphis, Tenn., Rational Treatment of Acute and Chronic Osteomyelitis; Open Reduction and Internal Fixation of Selected Fracture Cases.
Dr. William L. Estes Jr., Bethlehem, Pa., Acute Nonpenetrating Trauma of the Abdomen.
Dr. Elliott C. Cutler, Boston, Incomplete Intestinal Obstruction; Acute Appendicitis.
Dr. Samuel A. Levine, Boston, Rheumatic Heart Disease; Bedside Diagnosis of Cardiac Arrhythmias.
Dr. William R. Houston, Austin, Texas, Learned Reactions.
Friday morning October 27 there will be a symposium on preoperative and postoperative treatment presented by Drs. Ralph H. Major, Kansas City, Mo.; John S. Lundy and Lloyd H. Mousel, Rochester, Minn.; Walter G. Maddock, Ann Arbor, Mich.; John R. Paine, Minneapolis, and Dr. Estes.

NEW JERSEY

Society News.—Dr. Emil Novak, Baltimore, addressed the Hudson County Medical Society, Jersey City, October 3, on "Endocrine Aspects of Gynecology."—A symposium on "Newer Aspects of Preoperative and Postoperative Care" was presented before the Bergen County Medical Society, Hackensack, October 10, by Drs. Harry A. D. O'Connor, who discussed thyroid cases; John A. Lawler, abdominal cases; John H. Mulholland, intestinal obstruction, and Samuel Standard, fluid balance. All are members of the faculty of New York University College of Medicine.—Dr. Jesse Lynn Mahaffey, state health officer, Trenton, addressed the Atlantic County Medical Society October 13 in Atlantic City on diagnosis and treatment of syphilis.

NEW YORK

New Division of Cancer Control.—A new division of cancer control has been created in the state department of health with Dr. Louis C. Kress, Buffalo, as director. Organization of a statewide program of cancer control, authorized by legislation this year, will begin immediately under the direction of Dr. Kress. The law creating the new division includes an appropriation of \$35,000 for the conduct of three major activities: statistical, clinical and educational. The headquarters of the division are to be in Albany in the New York State Teachers' Association building. The law makes cancer a reportable disease upstate and provides for study of cancer distribution and study of the disease according to age, type and other characteristics. Tumor clinics are to be established in recognized general hospitals and consultants will be provided to aid in the establishment of clinics and their proper functioning. In addition a special effort will be made to study all possible relations between occupations and cancer. Dr. Kress since 1932 has been assistant director of the old division of cancer control in the state department.

District Meetings.—The Seventh District Branch of the Medical Society of the State of New York held its annual meeting at Canandaigua September 28. Four sound motion pictures portraying the work of Dr. Ephraim MacDowell, the story of Jenner and vaccination, discovery of insulin by Banting and Best, and the work of Semmelweis on sanitation in childbirth were shown. Addresses were made by Drs. Nathan B. Van Etten, New York, President-Elect of the American Medical Association, on "The Quality of Medicine"; Edward S. Godfrey Jr., state health commissioner, Albany, "Our Health," and Terry M. Townsend, New York, president of the state society, "Political Medicine." Demonstrations were presented as follows: surgical emergencies, Dr. John J. Moorhead, New York; care of premature infants, Dr. Burtis B. Breese Jr., Rochester; peripheral vascular diseases, Dr. Herman E. Pearce Jr., Rochester; physical therapy, Dr. Louis V. J. Lopez, Canandaigua, and occupational therapy, Dr. Raymond F. Wafer, Canandaigua.—The annual meeting of the Eighth District Branch of the Medical Society of the State of New York was held in Batavia October 5. Speakers on the program were:

Dr. Grover C. Penberthy, Detroit, Trauma and Low Back Pain.
Dr. George F. Cahill New York, Hematuria: Its Clinical Significance.
Dr. Albert D. Kaiser, Rochester, The Problem of Rheumatic Infection in Childhood.
Dr. Merrill C. Sosman, Boston, Roentgenology as an Aid in the Diagnosis of Heart Disease.

There was a discussion on "The Diagnosis and Therapy of the Frequent Gastro-Intestinal Lesions Met With in General Practice," with Dr. Abraham H. Aaron, Buffalo, as chairman. A discussion of the Western New York Indemnity Plan was opened by Dr. George R. Critchlow, Buffalo.

New York City

William H. Welch Lectures.—Dr. Herbert M. Evans, of the Institute of Experimental Biology, University of California, Berkeley, will deliver the second of the William H. Welch Lectures at the Mount Sinai Hospital October 24 on "Unsolved Problems in Anterior Pituitary Physiology." The first of this group was given October 20 on "New Light on the Biological Role of the Antisterility Vitamin E."

Personal.—Dr. Oswald L. Lowsley was made an Officier de l'Ordre National de l'Honneur et Merite by the president of Haiti September 12 in recognition of his services in instructing the Haitian medical profession in urologic surgery. He was also made an honorary professor in the medical school.—It is reported that the "Manual of Diseases of the Eye" by Dr. Charles H. May is being translated into Urdu by the Osmania University, Hyderabad, India, the tenth translation of the book into a foreign language. The sixteenth American edition has just been published.

Conference on Convalescent Care.—The committee on public health relations of the New York Academy of Medicine in cooperation with the Josiah Macy Jr. Foundation will hold a two day conference on convalescent care at the Academy November 9-10. The purpose of the conference is "to redefine the problem of convalescence in the light of recent progress in medical science and to explore the need for further research into the socio-economic and medical aspects of convalescent care." Admission to the conference sessions will be by invitation. A meeting will be held Friday evening November 10, at which the discussions will be summarized. Persons interested are invited to the evening meeting.

Regional Meeting of Railway Surgeons.—The New York and New England Association of Railway Surgeons will hold its forty-ninth annual meeting November 2-3 at the Hotel Commodore. The first day will be given over to clinics at the New York Post-Graduate Hospital under the direction of Dr. Thomas H. Russell. Speakers for the second day include:

Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C. Railway Surgeons and the Public Health.
Dr. Fred W. Geib, Rochester, N. Y., Acute Craniocerebral Trauma.
Dr. William E. Misher, Cleveland, Trauma in Transportation.
Dr. Tom Outland, Sayre, Pa., Treatment of Fractures of the Spine.
Dr. Albert B. Ferguson, New York, X-Ray Differentiation of Traumatic and Nontraumatic Lesions.

OKLAHOMA

New Health Officers.—Dr. John A. Morrow, Sallisaw, has been appointed deputy health commissioner of the Oklahoma State Health Department.—Dr. Joe Dorough, Haileyville, has been appointed health superintendent of Pittsburg County and Dr. Weldon K. Haynie, Durant, of Bryan County.

Annual Clinical Conference.—The Oklahoma City Clinical Society will present its ninth annual fall clinical conference October 30 to November 2. The lecturers will be:

Dr. Albert H. Aldridge, New York, obstetrics.
Dr. Edgar G. Ballenger, Atlanta, urology.
Dr. Lewellys F. Barker, Baltimore, internal medicine.
Dr. Lowell S. Goin, Los Angeles, roentgenology.
Dr. Harry S. Gradle, Chicago, ophthalmology.
Dr. John A. Kolmer, Philadelphia, pathology.
Dr. Frank H. Lahey, Boston, surgery.
Dr. Joe V. Meigs, Boston, gynecology.
Dr. Albert Graeme Mitchell, Cincinnati, pediatrics.
Dr. Emil Novak, Baltimore, endocrinology-gynecology.
Dr. Hobart A. Reimann, Philadelphia, internal medicine.
Dr. Erwin R. Schmidt, Madison, Wis., surgery.
Dr. Herman C. Schumm, Milwaukee, orthopedic surgery.
Dr. Rock Sleyster, Wauwatosa, Wis., President, American Medical Association, psychiatry.
Dr. Marion B. Sulzberger, New York, dermatology.
Dr. William A. Wagner, New Orleans, otolaryngology.

PENNSYLVANIA

New Medical Directors.—Dr. Harry L. Baker, Catasauqua, has been appointed medical director for Lehigh County, succeeding Dr. Eugene H. Dickenshied, Allentown.—Dr. Alfred L. Hoffmaster, New Castle, has succeeded Dr. Paris A. Shoaff, New Castle, as medical director of Lawrence County.—Dr. James B. Heller, Pottsville, has been appointed medical director of Schuylkill County.

Psychiatry Society Organized.—The Pennsylvania Psychiatric Society was organized at a meeting in Pittsburgh October 5. Dr. William C. Sandy, director of the state bureau of mental health, Harrisburg, was elected president and Dr. Henry I. Klopp, Allentown, president-elect. Dr. Leroy M. A. Maeder, Chancellor Hall, 206 South Thirteenth Street, Philadelphia, is secretary. In a statement at the organization meeting Dr. Sandy observed that the new society should exercise a statewide general leadership in psychiatry, being a coordinating body to which controversial and other questions of psychiatric interest may be referred for an authoritative opinion, should encourage general medical interest by participation in society meetings and should assist in developing and supporting proper psychiatric standards.

Philadelphia

Surgical Positions Filled at Jefferson.—Dr. Thomas A. Shallow, professor of surgery at Jefferson Medical College, has been appointed to the Samuel D. Gross chair of surgery at Jefferson, a position vacant since the death in 1933 of Dr. John Chalmers DaCosta. Newspapers also announce the appointment of Dr. George P. Müller, also professor of surgery, to the Grace Revere Osler chair of surgery. The Gross professorship was established in 1910 by Mrs. Maria Gross Horwitz, Baltimore, in honor of her father, professor of sur-

gery at Jefferson from 1856 to 1882. Dr. DaCosta held the chair from 1910 to his death in 1933. Dr. Shallow graduated at Jefferson in 1911 and Dr. Müller at the University of Pennsylvania School of Medicine in 1899.

Society News.—Dr. Alfred Blalock, Nashville, Tenn., gave the forty-fifth Mary Scott Newbold lecture of the College of Physicians of Philadelphia October 4 on "Shock."—Drs. Albert E. Bothe and Benjamin Lipshutz addressed the Philadelphia Academy of Surgery October 9 on "Renal Hypertension" and "Regional Enteritis" respectively.—Drs. Albert B. Ferguson, New York, and George E. Pfahler addressed the Philadelphia Roentgen Ray Society October 5 on "Characteristics of Bone Tumors" and "Treatment of Bone Tumors" respectively.—Speakers before the Obstetrical Society of Philadelphia October 5 were Drs. Walter Meredith Heyl on "Experiences with the Placental Blood Bank" and Edward F. McLaughlin, "Intermenstrual Bleeding, A Surgical Condition."

Pittsburgh

Hospital News.—Mercy Hospital celebrated its annual "Mercy Day" September 28. Dr. John H. Musser, New Orleans, spoke on coronary occlusion.

Society News.—The Pittsburgh Otolological Society held a joint meeting with the Cleveland Otolaryngological Club September 27, with Dr. Charles T. Porter, Boston, as the guest speaker on "Orbital Cellulitis."

UTAH

Special Assessment for Insurance Unit.—At a meeting of the house of delegates of the Utah State Medical Association September 4 the articles of incorporation of the Utah Physicians Service Company were approved and an assessment of \$15 was levied on each member of the society to provide for preliminary expenses. The work was carried out by the Medical Service Bureau and the medical economics committee of the society under authority given by the house of delegates at a special session Dec. 10, 1938. According to the *Rocky Mountain Medical Journal*, the action was taken to enable the profession to meet the demands for hospitalization on a pre-paid basis and if possible at least partial medical reimbursement.

WISCONSIN

State Medical Election.—Dr. Ralph P. Sproule, Milwaukee, was chosen president-elect of the State Medical Society of Wisconsin at the annual meeting in Milwaukee September 13-15 and Dr. Ray G. Arveson, Frederic, was installed as president. The next annual meeting will be held in Milwaukee September 18-19, 1940.

GENERAL

White House Conference on Child Health.—A recommendation that President Roosevelt be asked to call the White House Conference on Children into session January 18-20 was adopted at a special meeting of the planning committee of the conference in Washington October 6. The final session was originally scheduled for next spring.

Examination in Surgery.—The American Board of Surgery will hold an examination in Part II November 15 in Atlanta, Ga. The candidates will include only those living in the South. Additional information may be obtained from Dr. John Stewart Rodman, 225 South Fifteenth Street, Philadelphia.

Session on Medical Hydrology Postponed.—On account of the war in Europe the International Society of Medical Hydrology has postponed indefinitely its annual meeting which was scheduled to be held in Italy during October. Since the membership of the society is distributed largely through the countries now at war, it has been necessary to reduce the activities of the International Society of Medical Hydrology to the minimum. In keeping with this policy, the *Archives of Medical Hydrology* for October will not be issued at present. Correspondence addressed to the society at its regular address will receive attention, 22 Bedford, London, W.C.1.

Positions for Graduate Training in Obstetrics and Gynecology.—The American Board of Obstetrics and Gynecology receives from time to time information regarding available internships and assistant residencies. A number of such positions are available each year to men who wish to place their names on file with the board. In all instances a preliminary internship, preferably of the general, rotating type is necessary, and special internships or assistant residencies should be sought at least one year in advance. It is suggested that hospitals having positions open and men seeking such positions

for training communicate with the secretary. Applicants should submit names, addresses and brief biographic data. Address the American Board of Obstetrics and Gynecology, 1015 Highland Building, Pittsburgh (6).

Warnings Against Swindlers.—Harvard Medical School, Boston, has received reports that a magazine salesman has been soliciting subscriptions alleging that he is a student at Harvard and is attempting to earn money for further medical study. The medical school reports that this man, who calls himself Chester Wainwright, is not known and has never been a student there.—Reports have recently come from Missouri of a man who has swindled ophthalmologists in various towns by ordering glasses and making a check for a larger amount than the price. The physician makes change and the man never returns. The swindler has used the name W. C. Curran and appears to be a farmer. The check is usually for \$30. The man is about 5 feet 10 inches tall, weighs about 155 pounds, has light sandy hair and blue eyes and is smooth shaven with a ruddy complexion.

Meeting of Association of Medical Colleges.—The fiftieth annual meeting of the Association of American Medical Colleges will be held at the Netherland Plaza Hotel, Cincinnati, October 23-25, under the presidency of Dr. Willard C. Rappley, New York. The speakers will include:

Dr. Walter Bauer, Boston, The Tutorial System in the Harvard Medical School.

William H. Welker, Ph.D., Chicago, Graduate Medical Education.

Dr. Marion A. Blankenhorn, Cincinnati, Graduate Training in Internal Medicine in a Municipal Hospital.

Dr. Albert Graeme Mitchell, Cincinnati, Graduate Training in Pediatrics at the University of Cincinnati.

Dr. Mont R. Reid, Cincinnati, Training of Surgeons: Method in Use at the Cincinnati General Hospital.

Orren W. Hyman, Ph.D., Memphis, Tenn., Further Attempts to Refine the Methods of Selecting Medical Students.

Dr. Robin C. Buerki, Chicago, Internships and Residencies.

A symposium on student health service will be presented by Drs. John Sundwall, Ann Arbor, Mich., Nathan T. Milliken, Hanover, N. H., Edward S. Ryerson, Toronto, and Harold S. Diehl, Minneapolis.

Fund to Aid Infantile Paralysis Victims.—A gift of \$50,000 to aid handicapped children who are sufferers from infantile paralysis in twenty-five cities of the country has been announced by the Will Rogers Memorial Commission, according to the *New York Times* October 6. The funds were collected last spring from theater-goers in an appeal made in the principal theaters of the country. The gift is being made available through the local chapters of the National Foundation for Infantile Paralysis for emergency needs and for recovery treatment for handicapped children in the chapter areas. Of the shares distributed October 6 New York received the largest, amounting to \$14,595. Other cities in which disbursement took place are Los Angeles, San Francisco, Hartford, Springfield, Boston, Kansas City, Hoboken, Cleveland, Oklahoma City, Tulsa, Houston, Dallas, Milwaukee and Portland. Cities to receive their allotments later are Chicago, Newark, New Orleans, St. Louis, Cincinnati, Detroit, Philadelphia, Pittsburgh, Seattle and Washington. The commission also supports the Will Rogers Memorial Hospital, Saranac Lake, N. Y., and an emergency ward in the French Hospital, New York, for the use of theatrical people.

Society for Prevention of Blindness.—The National Society for the Prevention of Blindness will hold its annual meeting at the Hotel Astor, New York, October 26-28, under the presidency of William Fellowes Morgan. Among the speakers will be:

Dr. Joseph Minton, London, England, What Treatment of 7,000 Industrial Eye Injuries Has Taught Us.

Verne A. Zimmer, U. S. Department of Labor, Washington, D. C., The Interest of the Federal Government in Conserving the Sight of Industrial Workers.

Dr. Leonard Greenburg, New York, Poisonous Substances Affecting the Eyesight of Industrial Workers and How to Guard Against This Growing Hazard.

Dr. Willis S. Knighton, New York, Development of the Eye.

Dr. Otis J. Doupinett, Portland, Me., Early Supervision of Eye Muscle Control.

Dr. Philip M. Stimson, New York, What the Pediatrician Does to Save Sight.

Dr. James V. Cassady, South Bend, Ind., Prevention of Blindness Programs Developed by State Medical Societies.

Dr. Vonnie M. Hicks, Raleigh, N. C., What State Supervising Ophthalmologists Are Doing in the Prevention of Blindness.

Dr. Carl E. Rice, Washington, D. C., Possibility for Prevention of Blindness.

Dr. Harry S. Gradle, Chicago, Incidence and Distribution of Trachoma in the United States.

Dr. James G. Townsend, Washington, D. C., Treatment of Trachoma.

Foreign Letters

Medical Arrangements in Time of War

In a letter to the *Times*, Lord Dawson, late president of the Royal College of Physicians, discusses the problem of making the best use of the medical profession during a war which presents novel features. The task of registering physicians for varied duties has been performed by the British Medical Association during the past twelve months with conspicuous success. The Ministry of Health took the hospitals under its direction and mobilized physicians to staff them. It had the difficult task of urgent preparation for massed air attacks, involving rapid evacuation of casualties from the center to the periphery, side by side with care for the hospital needs of the civil population. For a time the latter faded and the big voluntary hospitals were denuded. But now organization is taking the place of improvisation. The Ministry of Health has taken steps to enable consulting physicians and surgeons to transfer from whole time to part time services in order that hospital and private patients may be served. It has to be remembered that, after the children, with those in charge of them, and the aged and infirm had been evacuated, the great majority of the citizens had to live and work and therefore required their hospitals. Services have been resumed with a proportion of the staffs.

Lord Dawson suggests the following modifications: 1. A portion of each hospital must always be available as a casualty clearing station. 2. The average stay in the hospital should be shorter. 3. Serious cases should also be provided for in the proximal outside hospital of the sector. (The dividing of London into sectors with the great hospitals at the center and affiliated hospitals in the country, into which the patients were evacuated for safety from air raids, has been described in a previous letter.) On the other hand, patients requiring special treatment, such as high-voltage roentgen therapy, must be gathered wherever such treatment is located. It has been agreed in principle that there is to be a united hospital service for the whole country. The army will provide directly for its sick and wounded in the theater of war, but in England they could be treated in the same hospitals as civilians, except slight and convalescent cases, which can be aggregated in convalescent hospitals subject to military discipline. This system would result in better service and save cost.

The supply of physicians is limited and has called for careful allotment. In particular the skill of specialists should not be wasted by needless duplication. Head and chest injuries are examples. Centers for both are being organized where not only they can be treated to the best advantage but where men of selected ability are being constantly trained to fill posts at home or over sea. If arrangements are left to military or civilian authorities, confusion will result, especially if a key man is put to wrong use. A small "intelligence" committee consisting of representatives of the army and its civilian medical services could act as a clearing house. Success in war depends more and more on knowledge and its application not only to medicine but to every other aspect of the struggle.

The Fate of Swallowed Foreign Bodies

Although many cases of swallowed foreign bodies have been reported, little has been written on the question whether they should be removed. At the Section of Surgery of the Royal Society of Medicine Mr. A. M. H. Siddons endeavored to answer this question by means of the records of three London hospitals—St. George's, the Royal Waterloo and the Belgrave, which have a high proportion of children's beds. It is children

and the insane who most frequently swallow foreign bodies. He collected records of 126 patients admitted to these hospitals. It should be borne in mind that these patients were selected by surgeons as sufficiently dangerous to require treatment as inpatients. It is not possible, therefore, to draw conclusions from them as to the percentage of all swallowed foreign bodies which require removal. Indeed, this cannot be ascertained, as many cases never reach the physician. In 107 of the 126 cases (85 per cent) the foreign bodies were passed naturally, and in only four did perforation or obstruction occur. The remaining thirteen foreign bodies were removed, as the surgeon considered it dangerous to leave them or because it did not appear to him that they would be passed naturally. These figures may be compared with American ones reported by Henderson and Gaston in the *Archives of Surgery* in January 1938. They found nine instances of perforation in about 800 cases, most of which were not admitted to the hospital. They emphasize that many of the patients never seek medical aid and that therefore this figure of about 1 per cent for perforation is too high. Siddons divided his cases into three groups: blunt objects (sixty), long objects (eighteen), sharp objects excluding open safety pins (forty) and open safety pins (eight). It is interesting how long blunt objects stop in one place in the alimentary canal, only to progress again for no apparent reason. It might be expected that objects which failed to pass the pylorus for a whole day would never do so, but in some cases they were watched in the stomach for weeks and then went on their way. The average time for the object to pass in the entire series was six days and in each group about the same. What is more important, they did not seem to do any harm while stationary. There are many records of insane persons and professional swallows who have retained objects in their stomachs for long periods without ill effects. In only one case of the series was a body arrested at the ileocecal region, causing intestinal obstruction. In the sixty cases of blunt objects there were eight operations for removal. Excepting the case mentioned there were no symptoms of harm. The operations were performed because the surgeons thought that the object would not pass, and had they been left probably most of them would have been passed naturally. Siddons thinks that there are very few objects able to pass down the esophagus which will not pass through, provided they are not sharp or unduly long. After the pylorus, the ileocecal region seems to be the only other likely site of arrest.

Long blunt objects include screws, nails and Kirby grips. They usually pass the pylorus but find the curves of the duodenum difficult. After this they usually find no obstruction. In the eighteen cases only one operation was performed: removal of a nail from the cecum on the second day. Siddons believes that it would have been passed naturally if it had been left. All the other objects were passed.

Sharp foreign bodies include needles, pins and open safety pins. Excluding the last there were forty cases, of which the object was passed naturally in thirty-seven. Not one perforated. In three cases the object was removed from the stomach because the surgeon did not think it safe to leave. The open safety pin presents a special problem. In four of the eight cases it was removed by operation, with one death. Of the other four, one perforated the stomach and was removed safely; the other three were passed naturally. Eight cases are not enough to form a basis for evaluating the risks, but there is no doubt that they are greater than with any other object. Siddons thinks, however, that they should be given a chance to pass, like other objects. Nearly all blunt objects pass naturally and should be given from four to six weeks. He does not agree with the recommendation to give bulky foods, as they may hasten obstruction and even in the case of sharp objects do not serve any useful purpose. He advises an ordinary diet and no purgatives.

Alterations in Medical Journals

As in the case of the lay press, medical journals have been obliged by the war to reduce the number of pages. The *British Medical Journal* has ceased to print its Key to Medical Literature. To economize, the Supplement will no longer appear as a separate inset. In it will be published information from the Central Emergency Committee of the British Medical Association, which was created to supply the medical needs of the fighting forces and civilians injured in air raids. It is probable that increasing economy of space will be necessary, so contributors are asked to be sparing of their words.

PARIS

(From Our Regular Correspondent)

Sept. 13, 1939.

French Medical Mobilization

Long before the war, France had prepared its medical mobilization. Without describing the medical organization in the army, I should like to show how the major health problems have been attacked and what has become, in the present war, of medicine and the medical profession.

A large number of France's 28,000 physicians have been drafted for the army. In fact, a law passed last year permits the government to commandeer the services of every Frenchman 18 years and over, including female physicians. The character of modern warfare is different from that of previous centuries. Until the French Revolution, war was a vocation and mercenary soldiers fought on limited territories. Their wounds were treated by "surgeons," one of whom was Ambroise Paré, the father of French surgery. Many others have left their mark in the history of medicine. Today the entire nation, except women and children, is engaged in war.

Few physicians have been exempt from military duty: 72 per cent serve in the national defense; 67 per cent of these wear uniforms; 5 per cent are civilians who function partly under army orders or those of the civil government. Accordingly, there remain about 6,000, many of whom are elderly or infirm. In consequence, many small towns and country regions have no medical service. Formerly, armies carried with them not only their "surgeons" but also their ambulances and to a certain degree their hospitals. Nowadays, except for establishments at the front which are, above all, centers of first aid and subject to quick changes, military health service coincides with civil health service. It includes large medical centers the equipment of which has been planned in times of peace and which utilize the hospital resources of peace times. Besides the wounded, the sick such as tuberculous persons have to be taken care of. From the medical point of view, both the tuberculous soldier and the tuberculous civilian are the same. Shifts of specialists have therefore been provided who look after civilian and military tuberculous patients in the existing sanatoriums, look after their recovery and follow them up after they leave the army.

What becomes, under these circumstances, of medical instruction? Students continue to enroll to the extent to which mobilization permits young men to undertake university studies, but the means of instruction have been greatly reduced. In large cities hospital training has reached a stage of anemia, partly because of the reduced population evacuated in large numbers and because of the abandonment of many class rooms as too exposed to the dangers of bombardment. The Faculty of Medicine of Paris had to move to Nantes to remain until further orders. Fifty-two per cent of its professional staff, 75 per cent of the agrégés, or assistants, and 90 per cent of the heads of laboratories or prosectors have enlisted. The students called to the colors there receive credits corresponding to their medical standing. Not only are arrangements made for examinations and thesis preparation but, in certain towns farther back from the front, courses of study lasting

several weeks are organized which permit the students to get ready for examinations before examiners who, likely enough, will consider emergency conditions. Precautions have been taken for laboratories. Fragile instruments, museum collections, ornamental objects and rare books have been stored in protected cellars. The Faculty of Medicine of Paris continues, but its activities have been largely curtailed. War destroys not solely human lives and human works. It undoes spiritual and moral values often more difficult of replacement than a railroad bridge or a model factory.

Defensive Measures Against Air Bombardments

In spite of all the measures provided to prevent hostile aircraft from releasing bombs over civil populations, some, estimated at 30 per cent, may reach their mark. Many, but not all, of these bombs will fall outside houses. A committee of passive defense, therefore, has been set up by law presided over by Marshal Pétain. Professor Tanon, of the department of health of the Faculty of Medicine, has been placed in charge in Paris, where every one has been removed from the city whose presence can be dispensed with, reducing the population from three million to somewhat more than one million. These will be protected, in case of bombardment, in subterranean shelters capable of supporting the shock at least of a bomb of 50 Kg. or a crumbling of 2,000 Kg. per square meter of surface. Against gas, masks have been distributed sufficient to protect against all known gases but offering no aid against carbon monoxide or hydrocyanic acid and perhaps equally insufficient against new gases which modern war chemistry may evolve. Most of the shelters are gas tight. However, medical aid stations have been prepared against possible gas infiltrations, "cave ins" and resulting panics. These medical aid stations cover extensive subterranean spaces, generally store-rooms or former quarries specially made over for their new use. They are supplied with small outside stations designed for those who have been infected with caustic gas. Aid stations are gas tight. Since gas might penetrate during the reception of patients, ventilation has been provided for from the outside air taken at a great altitude and above the gas level. This ventilation causes a higher pressure that protects the station against vitiated air. The output of the apparatus, each of which furnishes 600 cubic meters of air per hour, is calculated to carry 2 cubic meters of air hourly per cubic meter of the volume of space. The higher pressure, under these conditions, reaches between 2 and 6 mm. of mercury. The ventilators are set in motion by electricity, but, in case of a break in the current, apparatus with pedals resembling those of bicycles can assure functioning of the pumps. The air taken from the outside is analyzed every quarter of the hour by means of simple and rapidly functioning apparatus. If it is found vitiated—a thing of scant probability because of the height at which the air is taken—every one puts on his mask.

The patients, brought in by special outside crews, are assigned to one of three fundamental divisions: the wounded, the asphyxiated and the gassed. The wounded receive the necessary surgical attention in a simple operating room. Those asphyxiated are treated by the classic methods, inhalation of oxygen or carboxyl, camphorated oil or artificial respiration. Those overcome by mustard gas are copiously bathed and washed with chlorinated lime (10 per cent), undressed and doused with soap. The aids who have charge of them wear garments that protect them completely against yperite. After receiving first aid, the patients are assigned to special wards in Paris hospitals. Several kilometers from Paris a hospital with 5,000 beds receives the gassed whose treatment is likely to be prolonged. It is a model hospital from the point of view of perfect equipment for these treatments. Medical services thus organized are repeated on a smaller scale in all French cities. They seem to be adapted to all emergencies.

Primal Sutures of Wounds

Vassitch of Belgrade presented before the Academy of Surgeons an analysis of more than 19,000 traumas observed during 1929-1935, of which about 20 per cent were treated by primal suture. This operation does not entail grave accidents; however, it is necessary to take account of the object that caused the wound and whether the wound is clean or not. Vassitch adopts the classification proposed by Braine for flesh wounds. In wounds associated with fractures or complicated by osseous, articular or vascular lesions, bacterial virulence must be reckoned with. The essential prerequisite of the treatment of the wound is always its cleansing and the excision of contused tissue.

BERLIN

(From Our Regular Correspondent)

Aug. 30, 1939.

Congress of Surgeons

The opening address of this year's meeting of the Deutsche Gesellschaft für Chirurgie was by the chairman, Professor Nordmann, who is director of a hospital in Berlin. He cautioned against the exaggerated tendency toward new divisions of medicine. The efforts of neurologic surgeons to organize a distinct group was thwarted only by ministerial interference and by uniting them into a subdivision of the society.

The first paper was read by K. H. Bauer, of Breslau, on fractures of the base of the skull. Animals scarcely ever are subject to them and almost never through a fall. Such fractures are a "tribute to the progress of mechanics and traffic." Of those injured, 59 per cent were hurt in traffic accidents; 31 per cent of these died before medical attention could be given them; 66½ per cent of all skull fractures affect the base. The mortality in 4,200 observed cases was 39.2 per cent. The important diagnostic factor was the evidence of fracture revealed by the x-rays, and this was not so simple a matter. Three roentgenograms are required, especially the axial photograph with drooping head. Pressure on the brain can be relieved by intravenous injection of hypertonic salt and sugar solutions. Lumbar punctures in nearly all cases afford subjective and objective relief. Dandy and others, however, reject lumbar puncture in fractures of the base, on the ground that the brain may suffer further injury through change of position and because of the danger of secondary hemorrhages. As a last recourse trepanation is employed. Cushing ascribes to its early use the reduction of from 50 to 15.5 per cent in the mortality rate of fractures of the base of the skull. In about 10 per cent of the cases trepanation is indicated; extradural bleeding is a strong indication. In cases of subdural hematoma the mortality in surgical intervention is considerably higher. Of 512 subdural hematomas, fifty-two could not be diagnosed. According to recent statistics (2.5 per cent in 430 cases) danger of meningitis is low. Prognosis of employability after fractures of the base of the skull is discouraging. Frequently, according to the speaker, paralyzes of the nerves and injuries of the organs of sense can be proved; psychic disturbances are rare. Scar tissue formations of the brain may appear as a retarded injury and may induce epileptic hemiplegias. In the discussion of the paper Tönnis, a Berlin surgical neurologist, pointed out the results achieved in treating late epilepsy due to accidents. Success depends on selecting cases suitable for surgery. Only such epileptic patients should be operated on who have a dural bone callus; eleven of the twelve patients operated on did not suffer subsequent attacks. Of thirteen patients with skull fracture, eleven were permanently cured of attacks by surgery. In his paper on osteomyelitis Laewen, of Königsberg, pointed out that of late there has been a marked tendency to conservative therapy. Blood transfusion, suitable nutrition and rest are the most important conservative curative measures. Maggot therapy is also used.

Wilbolz, of Berne, read a paper on urogenital tuberculosis. He called attention to the fact that this was an open tuberculosis and dangerous for those in attendance on the patient. Hematogenic infection was here as significant as canalicular. Tubercle bacilli confined to the urogenital tract always seek to return. The seat of urogenital tuberculosis must be sought in the kidneys. The speaker favored early recourse to nephrectomy, which yielded permanent recovery in 80 per cent of the cases. Delayed surgery reduced this favorable proportion to 50 per cent. Consequently, early diagnosis of urogenital tuberculosis was of the greatest importance. Examination of the urine for tubercle bacilli often furnishes the answer, for tubercle bacilli are never excreted from a nontuberculous kidney. Tuberculous bacilluria is always the forerunner of tuberculosis of the kidney that is characterized by caseous cavities. If pyuria appears, nephrectomy must be performed. In benign cases tuberculosis will assume the "fibrous form," that is, contraction without caseation localized under the renal cortex; fibrous cortices without pyuria may cicatrize. Delay under medical observation was therefore advisable. If pyuria and slight functional disturbances accompany bacilluria, the caseous form of tuberculosis of the kidney is to be assumed and nephrectomy is in order. Bacilluria is almost always unilateral. This justifies the assumption that tuberculosis of the kidney is almost always unilateral.

Fromme, of Dresden, gave an exhaustive account of gastric ulcers, which have become more numerous and their seat nowadays is in the duodenum rather than in the stomach. Resection of ulcers of this type ought not to be insisted on as imperative, because of the danger of severing the choledochus. In 5 per cent of the cases, duodenal fistulas set in with a mortality of 50 per cent. The roentgenogram does not always clearly indicate whether an ulcer is operable. In nonoperable ulcers, resection for the purposes of elimination (according to Finsterer), also gastro-enterostomy, could be recommended. The disadvantages of this operation were that the ulcer remained, inviting the danger of hemorrhages and perforation. Likewise malignant degeneration constituted a possibility, though not a grave one. In the discussion that followed this paper, the greatest emphasis was put as usual on the results achieved by the different methods, but without agreement. Haberer, of Cologne, gave a report of his 3,373 resections of the stomach, of which 435 constituted corrective surgery. In 16 per cent of the cases, 211 extirpations of peptic ulcers of the jejunum resulted fatally. Peptic ulcers of the jejunum cannot be avoided in cases of gastro-enterostomy. He achieved the best results with the second procedure of Billroth, with anastomosis according to Roux.

Professor Lehmann, of Rostock, treated the problem of the relations of surgical clinics and x-ray institutes. Roentgenology is not a separate specialty but a medical ally. The type of men who are merely roentgenologists will disappear. X-ray institutes conducted independently easily lose contact with the clinics and yet the work done in the x-ray laboratory is part and parcel of the work done in the clinics. The directors of x-ray divisions should be members of the clinical staffs. He admitted the great difficulties of an organizational nature. For special examinations such as those of pyelography, ventriculography and myelography, the ward system of hospitals with central x-ray institutes was not practical. Roentgenologists should not by themselves determine indications. Lehmann thinks that the x-ray department of a hospital should be in charge of a roentgenologist who is subject to the director of the surgical division. This position was challenged by the chairman of the society of German roentgenologists, who stated that the greatest importance was attached to close cooperation but that the problems discussed by Lehmann were still too undarified to permit the roentgenologists to make a final decision. The comments of Professor Götze, surgeon in Erlangen,

on the degree to which specialization was being carried on deserve mention. In a general hospital, young physicians no longer had an opportunity to become acquainted with a large number of diseases requiring surgery, because these were taken care of by specialists. However, he continued to say, it was necessary that general surgery and the special fields of medicine supplement one another. Surgical clinics of universities should control all special fields of medical surgery, especially those that deal with accidents, fractures, orthopedics, urology and roentgenology, if for no other reason, at least for the training of students and assistants.

Professor König, of Würzburg, read an exhaustive paper on surgery and cancer control in which he took issue with those who were too pessimistic of the situation. Cancer of the stomach has the highest rate of cancer mortality with about 50 per cent. According to his computations, surgery performed on stomach cancers reduces mortality to 10 per cent. From 50 to 60 per cent of stomach carcinomas and 80 per cent of carcinomas of the rectum admit of surgical therapy. The important thing was to treat the disease in its early stages. The reason why results were reported covering only relatively short periods was principally that statistics do not extend sufficiently over larger periods of time. According to recent statistics based on investigations and inquiries made by seven well known hospitals, 424 of 1,260 former carcinomatous patients were designated as cured and free from ailments after from ten to twenty-five years. In considering these figures, one ought also to take account of the fact that a considerable number of those operated on for carcinoma had in the meantime died of other diseases. The number of those surgically cured of cancer would therefore be greater. The figures furnished by Professor Laewen, of Königsberg, by way of illustration are illuminating. Between 1935 and 1939, 18,864 female patients were examined serially for carcinoma of the breasts. Only 800 had new cancerous growths. In 3,767 gynecologic examinations, only four new carcinomas of the collum, one of the rectum and 106 suspected cases of the portio were discovered. Guleke, of Jena, found only thirteen verified cancerous formations in 200 similar examinations. A motion to organize special tumor clinics in Germany did not meet with the approval of the society. Other papers dealt with arthritis deformans, with treatment to be employed in bone fractures and with orthopedic problems.

Marriages

WILLIAM THOMAS HENDRIX, Spartanburg, S. C., to Miss Mary Emily Parker at Emory University, Ga., July 22.

RICHARD PHILIP CUSTER, Philadelphia, to Mrs. Claire Payzant Lohrke of Dartmouth, N. S., Canada, recently.

ROGER SHERMAN DOWNS, Saratoga Springs, N. Y., to Dr. ELINOR WHITNEY FOSDICK of New York, recently.

JAMES ROBERT FITZGERALD to Miss Myra Marcelle Sullivan, both of Chicago, at Davenport, Iowa, August 7.

WILLIAM C. HUFFMAN, Clarksburg, W. Va., to Miss Henrietta Claxon of Lawrenceburg, Ky., August 29.

WALTER WATSON ANTHONY VINKS to Mrs. Almary Seifert Lee, both of Lincoln, Calif., in Chicago, June 12.

JOHN WINSTON ADAMS JR., Chandler, Okla., to Miss Margaret Emily Harvey of Memphis, Tenn., July 17.

CLARENCE ALEXANDER KINNEY, Florence, S. C., to Miss Rosalie West Parks of Bennettsville, August 26.

BERNARD B. NEUCHILLER, Woodstock, Ill., to Miss Doris Purcell of Equality in Chicago, September 2.

WILLIAM S. MUSE, Lexington, Tenn., to Miss Loretta Greaney, of Worcester, Mass., September 2.

THOMAS A. GONDER JR., Milton, Mass., to Dr. SARAH HIGGINSON BOWDITCH of Oakland, Md., recently.

ROBERT GEORGE HEASTY, Wichita, Kan., to Miss Harriet Taliaferro Allen of Danville, Ky., July 22.

ROBERT BEALL HIGHTOWER, Washington, D. C., to Miss Russell MacDonald of Norton, Va., July 20.

FREDERICK R. DETTLOFF, Cloverdale, Ind., to Miss Kathryn Atkinson of Bloomington, September 30.

DONALD LURTON AREY, Danville, Va., to Miss Beverly Jeanne Barclay at Hempstead, N. Y., August 2.

FRED G. PATTERSON, Chapel Hill, N. C., to Miss Julia Baylor Shirley of Richmond, Va., September 5.

LEWIS EARL FRASER, Edmonton, Ky., to Miss Alice Jean Keith in Carthage, Miss., September 20.

HERMAN W. FARBER, Weldon, N. C., to Miss Henrietta Salsbury of Richmond, Va., August 30.

WILLIAM RAYMOND HAWKINS to Miss Hiawatha Louder, both of South Fork, Pa., September 4.

STEPHEN T. MANONG, Chamberlain, S. D., to Miss Gertrude Miriam Roe of Jackson, Mich., July 9.

JOHN COLE BURWELL JR., Greensboro, N. C., to Miss Jeanette Dorst of Austin, Minn., July 22.

JAMES EDWARDS CAMERON, Alexandria City, Ala., to Miss Edith Ellison at Hartsboro, August 1.

WILLIAM RAY MOORE to Miss Elizabeth Anderson Mason, both of Louisville, Ky., September 8.

NORMAN E. BASINGER to Miss Rosemary Williams, both of Elyria, Ohio, in Cleveland, June 26.

ROBERT MONROE McMILLAN, Candor, N. C., to Miss Dorothy Burchfield of Danville, Pa., July 12.

JOHN D. FITZGERALD, Roxboro, N. C., to Miss Betty Kathryn Offerman of Durham, September 5.

ROBERT F. DEARBORN, Orangeville, Ill., to Miss Barbara Burritt of Rockford, September 2.

EDWIN HALE THORNHILL, Durham, N. C., to Miss Pattie Marie Sills of Nashville, July 21.

RUTH EVANS BRINKER, Keokuk, Iowa, to Mr. Dan R. Hamady of Flint, Mich., July 29.

RANDOLPH PATTON MOORE, Lisbon, Ohio, to Miss Carol Barthelme of Cleveland, July 22.

THEODORE J. BRUEGGE, Kokomo, Ind., to Miss Catherine Lynch in Indianapolis, August 5.

GEORGE STREET McREYNOLDS JR. to Miss Sheddie Usher, both of Philadelphia, August 29.

JAMES HOMER LEIGH to Miss Kathryn Parks, both of Philadelphia, Miss., August 17.

JOSEPH L. HUNSBERGER to Miss Elizabeth Williams, both of Norristown, Pa., August 26.

ROBERT E. STONE, Chapel Hill, N. C., to Miss Frances Blakeney of Monroe, July 31.

WALTER LEE BRANDON to Miss Christina Ann Stewart, both of Poplar Bluff, Mo., July 7.

LUKE DENNIS GARVIN to Miss Helen Jane Chisholm, both of Bradford, Pa., October 7.

RUSSELL L. FINCH, Lansing, Mich., to Miss Althea L. Wysong of Holt, August 12.

WILLIAM LOUIS McLEOD to Miss Margaret Bland, both of Buies Creek, N. C., July 15.

JOHN W. BRADBURY to Miss Octavia Martinell, both of Galveston, Texas, August 5.

FRANK A. INDA, Omaha, to Miss Margaret M. Powers of Little Falls, N. Y., recently.

D. FOREST MOORE, Shelby, N. C., to Miss Eleanor Lyot Morton of Terrell, July 26.

HENRY EDWARD HENGEL, Amherst, Ohio, to Miss Grace Null of St. Louis, July 24.

LEROY W. CHILDS, Atlanta, Ga., to Miss Nancy Williams, Lake Kerr, Fla., August 5.

WILLARD E. FISCHER, Detroit, to Miss Barbara Jeanne Coan of Gladwin, Mich., July 29.

TIMOTHY F. P. LYONS, Boston, to Miss Anna Doherty of Milton, Mass., recently.

JULIUS FOLDES, Nanticoke, Pa., to Miss Mary Murphy of Oak Lane, August 19.

WILLIAM J. DONALD, Brewton, Ala., to Miss Vivian Frazier of Mobile, August 4.

ARTHUR FEITELL to Miss Freda Joyce Prichap, both of New York, September 12.

HAROLD ABRAMSON to Miss Lucy Kahn, both of New York, August 10.

Deaths

Algernon Coolidge ☉ Boston; Harvard Medical School, Boston, 1886; clinical instructor of laryngology, 1893-1906, assistant professor, 1906-1911, professor, 1911-1925, and since 1925 professor emeritus at his alma mater; professor of laryngology emeritus at the graduate school; member of the New England Otolaryngological and Laryngological Society and the American Clinical and Climatological Association; past president of the American Laryngological Association; fellow of the American College of Surgeons; for many years on the staff of the Massachusetts General Hospital; author of "Diseases of the Nose and Throat" published in 1915; aged 79; died, August 16, of heart disease and arteriosclerosis.

Wilbur Ashley McPhaul ☉ Jacksonville, Fla.; University of Nashville (Tenn.) Medical Department, 1904; state health officer; served as health officer of Robeson County, N. C.; in 1919 was director of rural sanitation work with the Alabama State Board of Health, becoming in the same year health officer of Montgomery; in 1920 was appointed health officer of Charlotte, N. C.; in 1931 he resigned to become field director of the U. S. Public Health Service; health officer of Pensacola for many years; at one time member of the state legislature of North Carolina; past president of the Florida Public Health Association; aged 60; died, August 1, in a local hospital.

Lawrence Taylor Price ☉ Richmond, Va.; Medical College of Virginia, Richmond, 1903; emeritus professor of clinical urology at his alma mater; president of the Virginia Urological Society; member of the American Urological Association; urologist to the Johnston Willis Hospital; on the staffs of the Memorial, St. Philip, Dooley and City Home hospitals, Retreat for the Sick Hospital and Tucker Sanatorium; consultant urologist to the Pine Camp Hospital, Brook Hill, Southside Community Hospital, Farmville, and the Westbrook Sanatorium; aged 58; was killed, August 15, when he fell from a fifth story window.

Maurice Joseph Gelpi, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1911; fellow of the American College of Surgeons; past president and secretary of the Orleans Parish Medical Society; instructor and assistant professor of gynecology at his alma mater, 1911-1916; professor of surgery, Loyola Post Graduate Medical School in 1921; editor in chief of the *New Orleans Medical and Surgical Journal* from July 1922 to June 1923; aged 56; served in various capacities on the staffs of the Charity Hospital and the Hotel Dieu, Sisters' Hospital, where he died, August 9, of cardiovascular disease and cerebral hemorrhage.

Frederick Stauffer, Monterey, Calif.; Kentucky School of Medicine, Louisville, 1893; member and past president of the Utah State Medical Association; formerly member and president of the Utah State Board of Health and Salt Lake County Medical Society; member of the American Academy of Ophthalmology and Otolaryngology; member and past president of the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; surgeon to the Dr. W. H. Groves Latter-Day Saints Hospital, Salt Lake City, for many years; aged 72; died, July 20.

Pio H. Laporte, Edmundston, N. B., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1901; minister of health and labor for the New Brunswick government; past president of the New Brunswick Medical Society; New Brunswick representative on the Medical Council of Canada; for many years mayor of the town and chairman of the school board; aged 59; died, July 29, in a hospital at St. Basile, of injuries received in an automobile accident.

Louis Mervin Maus ☉ Colonel, U. S. Army, retired, Rockville, Md.; University of Maryland School of Medicine, Baltimore, 1874; entered the army as assistant surgeon in 1874 and rose through the various positions to that of colonel in the medical corps in 1907; veteran of the Spanish-American and World wars; was awarded the Distinguished Service Medal for service among the Indians; retired May 8, 1915, by operation of law; aged 88; died, August 3, of obstructive jaundice.

Frederick Eugene Trotter ☉ Honolulu, Hawaii; University of Virginia Department of Medicine, Charlottesville, 1895; member of the House of Delegates of the American Medical Association in 1924 and 1930; commissioner of the Hawaii Board of Health and past president; past president of the State and Provincial Health Authorities of North America; veteran

of the Spanish-American War; formerly surgeon in the U. S. Public Health Service; aged 66; died, August 7, of heart disease.

John Andrew Evert ☉ Glendive, Mont.; University of Minnesota Medical School, Minneapolis, 1913; past president of the Medical Association of Montana and past president and secretary of the Eastern Montana Medical Association; fellow of the American College of Surgeons; served during the World War; chief surgeon of the Northern Pacific Hospital; aged 54; died, August 17, of plasma cell myeloma.

James Homer Buckley ☉ Fort Smith, Ark.; Tulane University of Louisiana School of Medicine, New Orleans, 1896; member of the American Academy of Ophthalmology and Otolaryngology; past president of the Sebastian County Medical Society; on the staffs of St. Edward's Mercy and of the Sparks Memorial Hospital; aged 64; died, July 31, of heart disease.

William Lytle Ross ☉ Omaha; Rush Medical College, Chicago, 1883; Bellevue Hospital Medical College, New York, 1887; member of the Radiological Society of North America; professor of dental neurology at the Creighton Dental College, 1905-1922; aged 80; died, August 26, in the Nicholas Senn Hospital of carcinoma of the head of the pancreas.

Graham Wall Diggs, Wetumka, Okla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1905; member of the Oklahoma State Medical Association; formerly secretary of the Hughes County Medical Society; mayor of Wetumka; served during the World War; aged 59; died, August 18, in the Veterans Administration Facility, Muskogee.

Robert Swan Killough ☉ Amarillo, Texas; Eclectic Medical Institute, Cincinnati, 1896; fellow of the American College of Surgeons; past president of the Potter County Medical Society; aged 72; on the staffs of the Northwest Texas Hospital and St. Anthony's Sanitarium, where he died, August 24, of a fractured hip received in a fall.

Thomas Sampson Royster ☉ Henderson, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1916; fellow of the American College of Surgeons; at one time passed assistant surgeon lieutenant in the United States Navy; on the staff of the Maria Parham Hospital; aged 48; died, August 1, of coronary thrombosis.

John Buis ☉ Pender, Neb.; University of Nebraska College of Medicine, Omaha, 1907; past president of the Cedar-Thurston-Wayne-Dixon-Dakota Counties Medical Society; served during the World War; aged 60; died, August 7, in the Immanuel Deaconess Institute, Omaha, of Hodgkin's disease and cerebral hemorrhage.

Robert Lee Kunkle, Piqua, Ohio; Ohio Medical University, Columbus, 1902; member of the Ohio State Medical Association; served during the World War; formerly city physician and health officer; aged 63; on the staff of the Memorial Hospital, where he died, August 2, of cirrhosis of the liver.

Barrie Samuel Rankin ☉ Kingwood, W. Va.; Baltimore Medical College, 1907; past president of the Preston County Medical Society; at one time member of the state legislature; served during the World War; formerly superintendent of the state hospital at Spencer; aged 67; was drowned, August 22.

Frederick William Hagney ☉ Newark, N. J.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893; aged 71; on the staff of Hospital of St. Barnabas and for Women and Children, where he died, August 26, of chronic myocarditis and arteriosclerosis.

Joseph Hubbard Saunders ☉ Williamston, N. C.; University College of Medicine, Richmond, 1905; past president of the Martin County Medical Society; served during the World War; formerly county health officer; aged 56; died, August 3, in a hospital at Richmond, Va., of hepatitis.

Thomas Leo Caldronney, Ridgefield Park, N. J.; University and Bellevue Hospital Medical College, New York, 1917; member of the Medical Society of New Jersey; on the staff of the Hackensack (N. J.) Hospital; aged 46; died, August 2, in Pompton Lakes of acute coronary thrombosis.

Alden J. Brace, Vici, Okla.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1900; member of the Oklahoma State Medical Association; aged 66; died, August 7, in the Shattuck (Okla.) Hospital following an operation for ruptured appendix.

Emil George Vrtiak ☉ Chicago; Rush Medical College, Chicago, 1920; associate clinical professor of medicine at his alma mater; on the staff of the Lutheran Deaconess Home and Hospital; aged 48; died, August 7, in the Presbyterian Hospital of coronary thrombosis.

John H. Colay, Morrilton, Ark.; University of Arkansas School of Medicine, Little Rock, 1911; member of the Arkansas Medical Society; aged 58; on the staff of St. Anthony's Hospital, where he died, August 16, of injuries received when he fell down an elevator shaft.

John Thomas Denton, Sanford, Fla.; Memphis (Tenn.) Hospital Medical College, 1902; member of the Florida Medical Association; formerly secretary of the Seminole County Medical Society; aged 60; died, August 3, in the Greenville (S. C.) General Hospital.

Robert Newhall Smith, Hollis, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1897; aged 67; died, July 30, of a streptococcal infection resulting from a fall which forced the pipe he was smoking through the back of his throat.

Joseph Ambrose Brady, New York; Long Island College Hospital, Brooklyn, 1903; member of the Medical Society of the State of New York; on the staffs of the Misericordia Hospital and St. Vincent's Hospital; aged 62; died, August 26, of heart disease.

Gaston Day, Jacksonville, Fla.; Johns Hopkins University School of Medicine, Baltimore, 1906; member of the Florida Medical Association and the American Society of Anesthetists; served during the World War; aged 57; died, August 5, of coronary occlusion.

Edward Augustus Stratton @ Danbury, Conn.; University of the City of New York Medical Department, 1883; fellow of the American College of Surgeons; surgeon to the Danbury Hospital; aged 77; died, July 9, of carcinoma of the stomach.

Henry William Held, Vincennes, Ind.; Medical College of Ohio, Cincinnati, 1894; member of the Indiana State Medical Association; formerly county coroner; aged 69; died, August 9, in the Good Samaritan Hospital of diabetic gangrene.

Robert Lee Cater Jr., Greensboro, N. C.; Emory University School of Medicine, Atlanta, Ga., 1916; member of the Medical Society of the State of North Carolina; aged 44; was found dead, August 8, of acute dilatation of the heart.

John Frederick Cumming, Morris, Minn.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1922; member of the Minnesota State Medical Association; aged 41; died, July 12, of hypertension and cerebral hemorrhage.

James Allen Ballard, San Francisco; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1904; served during the World War; on the staff of the Veterans Administration Facility; aged 54; died, July 5.

Edward B. Kaple, Camillus, N. Y.; Cleveland University of Medicine and Surgery, 1895; past president of the Onondaga County Medical Society; for many years on the staff of the Syracuse Memorial Hospital; aged 66; died, July 26.

Hudson D. Bishop @ Cleveland; Homeopathic Hospital College, Cleveland, 1890; formerly professor of surgery at his alma mater; for many years on the staff of the Maternity Hospital; aged 72; died August 17, of heart disease.

Oliver James Wood, Cleves, Ohio; Miami Medical College, Cincinnati, 1883; past president of the county board of health and the Cleves-North Bend school district; aged 87; died, August 8, of arteriosclerosis and heart disease.

Rufus Joel Danner, Terre Haute, Ind.; Kentucky University Medical Department, Louisville, 1901; member of the Indiana State Medical Association; served during the World War; aged 65; died, August 26, of heart disease.

Joseph Maurice Allen, Rosholt, S. D.; Hamline University Medical Department, Minneapolis, 1901; aged 72; died, August 8, in St. Francis Hospital, Breckenridge, Minn., of gangrenous appendicitis and coronary occlusion.

Oliver S. Olson, Gary, Ind.; University of Illinois College of Medicine, Chicago, 1912; member of the Indiana State Medical Association; served during the World War; aged 55; died, August 20, of carcinoma of the intestine.

Delbert Frederick Dumas, Bemidji, Minn.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; aged 60; died, August 8, of hypertensive heart disease and cerebral thrombosis.

Nathan Browne Hammond, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1903; demonstrator of pharmacy, 1905-1910, and lecturer, 1910-1911, at his alma mater; aged 62; died, July 18.

Calvin Ashley Traver, North Little Rock, Ark.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1897; aged 66; died, July 30, of pneumonia, intestinal obstruction and appendicitis.

Michael A. Cohn, San Diego, Calif.; College of Physicians and Surgeons, Baltimore, 1893; member of the Medical Society of the State of New York; aged 71; died, July 10, at La Jolla.

Albert E. Hussey, Cincinnati; Medical College of Ohio, Cincinnati, 1901; formerly connected with the U. S. Veterans Bureau; aged 59; died, August 1, of cerebral hemorrhage.

Frederick Walter Mason, Brandon, Vt.; Keokuk (Iowa) Medical College, 1897; aged 64; died, August 7, in a hospital at Rutland of gastric hemorrhage and diabetes mellitus.

Clarence Earl Hamel, Kalispell, Mont.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; aged 66; died, July 29.

Frederick Elisher Salvage, La Moure, N. D.; Rush Medical College, Chicago, 1892; member of the North Dakota State Medical Association; aged 72; died, July 14.

Ida Rebecca Brigham, Brookline, Mass.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; aged 89; died, July 3, of coronary sclerosis.

James Cannon Greene, Greenville, N. C.; Medical College of Virginia, Richmond, 1900; aged 70; died, August 15, in the Pitt General Hospital, of chronic myocarditis.

Henry John Abele, Lakewood, Ohio; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1898; aged 80; died, August 4, of heart disease.

William Albert Berry, Chicago; Rush Medical College, Chicago, 1903; aged 60; on the staff of St. Bernard's Hospital where he died, August 26, of angina pectoris.

William G. Ferguson, Rockville Centre, N. Y.; Fort Wayne (Ind.) College of Medicine, 1891; formerly school physician in Fort Wayne, Ind.; died, July 31.

Arthur Peter Shellman, Binghamton, N. Y.; University of the City of New York Medical Department, 1894; aged 69; died, July 16, of coronary thrombosis.

Louis H. Graham, Waxahachie, Texas; Louisville (Ky.) Medical College, 1889; member of the State Medical Association of Texas; aged 76; died, August 6.

Robert Brown Whiteside, Lott, Texas; College of Physicians and Surgeons, Baltimore, 1889; aged 73; died, July 28, of cerebral hemorrhage and arteriosclerosis.

La Forest Ethelbert Phillips @ Palo Alto, Calif.; Cooper Medical College, San Francisco, 1899; on the staff of the Palo Alto Hospital; aged 63; died in July.

Adam Henry Straub, Brooklyn; Long Island College Hospital, Brooklyn, 1889; aged 73; died, July 2, in the Wyckoff Heights Hospital, of diabetes mellitus.

John Darius Jackson, Perryville, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1881; aged 80; died, July 25, in Terrell of senility.

Noble Hind Hill, Boston; Boston University School of Medicine, 1892; aged 79; died, July 13, in the Boston City Hospital, of cerebral thrombosis.

Frank Walters Stuart, Seattle; Homeopathic Hospital College, Cleveland, 1890; aged 82; died, July 26, of cerebral hemorrhage and hypertension.

Henry Hertel, East St. Louis, Ill.; St. Louis Medical College, 1878; member of the Illinois State Medical Society; aged 89; died, August 22.

Mary Elizabeth Rosenberg Nelson, San Diego, Calif.; University of Nebraska College of Medicine, Omaha, 1897; aged 83; died, July 15.

William D. Mace, La Fayette, Ind.; Medical College of Indiana, Indianapolis, 1889; aged 71; died, July 31, of acute dilatation of the heart.

Sae T. Greenberg, Cleveland; Medizinische Fakultät der Universität, Wien, Austria, 1908; aged 59; died, July 19, of coronary thrombosis.

Frank R. Falby, Charlotte, Vt.; Baltimore Medical College, 1897; aged 72; died, July 30, of cerebral hemorrhage and arteriosclerosis.

David Scott Hoig, Oshawa, Ont., Canada; University of Toronto Faculty of Medicine, 1880; aged 85; died, August 7.

Moses Wiesh, San Antonio, Texas; Missouri Medical College, St. Louis, 1897; aged 85; died, August 14, of myocarditis.

C. C. Witt, Lake City, Fla.; Medical College of the State of South Carolina, Charleston, 1909; aged 55; died, July 19.

Charles Warwick McVicar, Winnipeg, Man., Canada; Manitoba Medical College, 1924; aged 38; died, August 12.

Sidney A. Hoesman, Cozaddale, Ohio; Cincinnati College of Medicine and Surgery, 1901; aged 79; died, August 4.

Bureau of Investigation

TWO ABORTIFACIENTS BARRED

1. Cosmo Carrano and His D. M. C. Pills

From New Haven, Conn., Cosmo Carrano, a quack said by government officials to have a criminal record, did a medical mail-order business under the trade style "Oceanview Medical Products" selling "D. M. C. Pills." In the opinion of Judge Vincent M. Miles, Solicitor for the Post Office Department, it was apparent that the advertising of this product indicated that it was an abortifacient. As he put it: "The evidence in this case shows that it is the promoter's [Cosmo Carrano's] intention to hold out his preparation as an abortifacient and that he is selling it through the mails for that purpose."

Carrano, according to Judge Miles's memorandum, had previously been convicted on five different occasions of

Some of Carrano's advertising.

possessing, selling or shipping obscene matter. According to the same memorandum, the Post Office Department issued a fraud order against Carrano in March 1936 for operating a mail-order swindle in the sale of books, pictures and cartoons.

In 1937, according to material in the files of the Bureau of Investigation of the American Medical Association, Carrano entered into a stipulation with another government agency, the Federal Trade Commission, to "discontinue representing directly or by reasonable implication that his preparation [D. M. C. Vegetable Pills] is an abortifacient." But Carrano was still selling his D. M. C. pills in 1939 when the Post Office Department again took a hand. He was called on to show cause on Feb. 23, 1939, why the postmaster at New Haven should not be instructed to stamp all mail addressed to Oceanview Medical Products "FICTITIOUS" and return all such mail to the senders or else send it to the Division of Dead Letters at Washington.

On February 21 Carrano's attorney, Walter J. McCarthy of New Haven, addressed a letter to the Post Office Department, stating that his client would be willing to sign a stipulation—another one!—agreeing to discontinue his scheme.

Naturally the Post Office officials took the attitude that, as they put it, "no reliance might be placed upon any promise" made by Carrano. Mr. McCarthy was notified that a hearing would be held at Washington on February 28. On that date Mr. McCarthy appeared on behalf of Carrano and a hearing that consumed half a day was held.

As Judge Miles brought out in his memorandum to the Postmaster General, Carrano's published testimonials were "shown to be from married women and indicate that the preparation [D. M. C. pills] sold in this scheme had relieved cases of delayed menstruation of two months and over, the inference being throughout such testimonials that the preparation [D. M. C.] actually accomplished abortion in such instances." The memorandum further stated that in a number of instances Carrano had sent his D. M. C. pills through the mails in cases in which they were expressly ordered for the purpose of effecting an abortion. (Italics ours—Ed.)

The evidence showed, according to the memorandum, that Cosmo Carrano was violating 18 U. S. Code 339 and 334, statutes that specifically prohibit the advertising and sale through the mails of any matter to be used for the purpose of producing abortion. On March 6, 1939, the mails were closed to Oceanview Medical Products.

2. "Bornock's Tablet Treatment"

On Jan. 21, 1939, Olaf M. Bornstad of Minneapolis was called on by the Post Office Department to show cause why the postmaster at Minneapolis should not be instructed to stamp all mail addressed to Bornstad's "Bornocks Company" as "FICTITIOUS" and either return it to the senders or direct it to the Division of Dead Letters at Washington.

On January 28 Bornstad's attorney, Olaf L. Bruce of Minneapolis, wrote the Post Office Department a letter in which he transmitted a statement from Bornstad, waiving a hearing and indicating a willingness to have all mail addressed to his company returned to senders. In the memorandum to the Postmaster General from the Solicitor of the Post Office Department, Judge Vincent M. Miles, it is brought out that Olaf M. Bornstad under the Bornocks Company trade style had been advertising and selling through the mails "Bornock's Tablet Treatment" as a means of producing abortion.

Bornstad solicited business, stated Judge Miles, "by the use of newspaper advertisements" and letters. Unfortunately the names of the newspapers that became *particeps criminis* with Bornstad were not given. On Feb. 15, 1939, the mails were closed to Bornstad's trade style, Bornocks Company, and its officers and agents as such, because the business was a violation of 18 U. S. Code 339 and 334.

THE INDIAN DRUG STORE FRAUD

From March 1934 until Jan. 17, 1939, Armon S. Compton of Philadelphia, who is said to claim that he is a pharmacist, had been selling two nostrums through the mails. The "patent medicines" in question were called, respectively, "Presta Tablets" and "Re-Gens Tonic Compound." These were sold not under Compton's own name but under the trade style "Indian Drug Store." The location was 1440 South Street and it appears that it was a small "botanical drug store" from which Compton also sold locally a general line of herbs.

Presta Tablets were supposed to restore lost sexual vitality, while Re-Gens Tonic Compound was apparently recommended for everything from hot flashes to cold feet. When analyzed the tablets were reported to contain damiana, strychnine, zinc phosphide, iron (ferric) oxide and a small amount of the inevitable cantharides (Spanish flies). The tablets were supposed to cure lost sexual vitality whether the condition was due to tuberculosis, diabetes, venereal disease, old age or to psychic causes.

The Re-Gens Tonic was reported on analysis to contain gentian, iron (ferric) oxide, salicylic acid and epsom salt—especially epsom salt—and a little calcium, sodium and potassium. The stuff was essentially a laxative. As such a mixture would not "keep your Blood, Stomach, Liver, Kidneys and Bowels in good condition" and would not enable persons to

"avoid Constipation, Dyspepsia, Sour Stomach, Bad Breath, Malaria, Sick Headache, Kidney Troubles, Liver Complaint, Loss of Appetite, Rheumatism, Lamé Back, Impure Blood, Pimples, Eczema, Boils" and so on, the scheme was declared a fraud and the mails were closed to the Indian Drug Store on the date given in the opening paragraph.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HYPOTENSION

To the Editor:—A woman of 45 who is otherwise healthy has a blood pressure of 80/42. What should be done to raise this blood pressure? Would thyroid extract be indicated?

I. Herman, M.D., Newark, N. J.

ANSWER.—It has been customary to separate chronic arterial hypotension into two types (primary, or essential, and secondary), but such distinction is largely arbitrary. The pathogenesis and disturbed homeostatic mechanisms are alike; the conditions differ only in obviousness of etiology. In some instances of habitual hypotension the causation is fairly obvious and in others obscure. The etiology of hypotension involves numerous factors. These are divisible into predisposing (constitutional) factors and provoking (initiating) influences. In clinical instances in which the provoking factors are obscure the predisposing causes usually predominate (Stieglitz, E. J.: *Abnormal Arterial Tension*, New York, National Medical Book Company, Inc., 1935).

To be effective, therapy must be based on correction or amelioration of the cause. In the present instance it must be assumed that no obvious intoxications, infections, dehydration or metabolic disturbances exist and that the hypotension is habitual and continuous rather than merely evidence of a transient depression of vascular tone. Careful search for sources of intoxication such as foci of infection, prolonged fatigue, tuberculosis and habitual use of depressant drugs should be conducted. Excessive self medication with any of the many generally available barbiturates, bromides and other sedatives is not an infrequent factor in habitual hypotension, but it is rarely admitted by the patient. The cardiac reserve is an important consideration, and one would wish to know the circulatory response to effort and the character and rate of the pulse. Should such clinical studies fail to elicit evidence as to the causation of the hypotension, then and only then supportive and stimulative therapy is justified.

Hypotension per se is not a disease. It is a physiologic state deviating from the accepted normal. Moderate hypotension may be and often is perfectly compatible with health and well-being. Only when hypotension is sufficient to impair circulatory efficiency and cause symptoms is one justified in instituting therapy; it is with the patient and not with the level of arterial tension that one should be concerned. Rest is probably the most effective measure. Hypotensive persons have a distinctly lowered endurance. Fitting the pace of living to the patient's capacity of activity can often do more good than any other measure. This applies to mental and emotional as well as physical strains. The program of daily routine can often be modified to yield short rest periods.

Improvement of nutrition is important. Many of these patients are grossly undernourished, while others are flabby and overweight. A diet planned to prevent constipation is desirable. Anemia, even of minor degree, should be energetically combated. Hypotension is frequently associated with deficient oxygenation. Apocamnosis encourages sedentary habits. Fresh air and exercise appropriate to the patient's strength are valuable.

Drugs are but auxiliaries in the management of habitual hypotension and must not be relied on to the exclusion of other measures. Strychnine sulfate (0.6 mg.) or the old-fashioned but effective elixir of iron, quinine and strychnine before meals may be continued profitably for weeks. Epinephrine has too fleeting an action to be applicable to the control of chronic hypotension; furthermore, it must be administered parenterally. Ephedrine salts and benzedrine have undesirable side effects such as insom-

nia, cardiac excitation and excessive cerebral stimulation and are thus best avoided. Thyroid extract is definitely indicated when the basal metabolic rate is low. It should never be prescribed without controlling observations of the basal metabolic rate, the pulse rate and the sense of well-being of the patient. Frequently it is tolerated surprisingly well by those whose metabolic rate is normal, and although the rate is but little increased considerable clinical benefit is obtained. The precaution of repeated observations of such patients should not be neglected. Appreciation of the fact that the discovery and correction of the causal influences is of major importance in treatment will insure better therapeutic results. The therapy required for each patient must be individualized.

BILE SALTS

To the Editor:—Could you give me a formula for a preparation of bile salts to be used in cases of chronic cholecystitis?

Albert Kaplan, M.D., Kech, Mo.

ANSWER.—Normal human bile obtained from the common or hepatic duct contains approximately 1 per cent of bile salts; in the bile in the gallbladder the concentration is from six to ten times greater. These bile salts consist chiefly of sodium glycocholate, sodium taurocholate, sodium cholate, sodium chenodeoxycholate and some sodium desoxycholate. Other bile salts are present in minute traces and there may also be small amounts of the free bile acids themselves. Ordinarily the ratio between sodium glycocholate and sodium taurocholate in normal human bile is about 3:1.

Ox bile, from which most commercial preparations of bile salts are made, does not differ greatly in composition from human bile in respect to the glycocholate:taurocholate ratio. Theoretically it would be possible to prepare a mixture of bile salts which would correspond closely in composition to that of normal human bile but to do so would be an expensive and difficult process.

Schmidt and his associates (Schmidt, C. R.; Beazell, J. M.; Atkinson, A. J., and Ivy, A. C.: *The Effect of Therapeutic Agents on the Volume and the Constituents of Bile*, *Am. J. Digest. Dis. & Nutrition* 4:613 [Nov.] 1938), working on dogs, found that preparations of conjugated bile acids are superior stimulants to the flow of bile and produce an increased excretion of normal biliary constituents. The oxidized unconjugated preparations increase the aqueous fraction of bile but result in an absolute decrease in the output of natural bile acid.

FORMATION OF GALLSTONES IN COMMON DUCT

To the Editor:—At a recent meeting the following questions elicited considerable discussion: Do stones form in the common duct of previously cholecystectomized patients or were such stones present and undiscovered at the time of operation? Why is symptomatic relief more pronounced when the gallbladder with stones is removed than when the "stoneless" or nonfunctioning gallbladder is taken out?

J. E. Morgon, M.D., Cleveland.

ANSWER.—It is probable that most stones found in the common duct of previously cholecystectomized patients represent stones that were present and undiscovered at the time of the original operation. There is conclusive evidence that stones may grow in the common duct and reach a large size and that, following their removal, a recurrence of similar large stones may take place, even though the gallbladder has been previously removed.

According to the observations of Phemister, Aronson and Pepinsky (*Ann. Surg.* 109:161 [Feb.] 1939), stone formation in the common duct is usually preceded by stone formation in the gallbladder and is set up after calculi have passed into the common duct with the resultant obstruction and infection. Rarely, stone formation may occur in the common duct independent of cholelithiasis, as in cirrhosis of the liver (Judd, *McIndoe and Marshall: Surgery of the Biliary System*, in *Lewis's Practice of Surgery*, Hagerstown, Md., W. F. Prior Company, Inc., 1929, vol. 7, chapter 2) or in carcinomatous obstruction of the ducts (Lampert, Ralph, and McFetridge, Elizabeth M.: *Carcinoma of the Hepatic Duct*, with Report of Additional Case, *Am. J. Cancer* 21:534 [July] 1934. Marshall, J. M.: *Tumors of the Bile Duct*, *Proc. Staff Meet., Mayo Clin.* 6:191-192 [April 1] 1931), and the stones may even form in the intrahepatic ducts. Phemister and his associates found that the stones which form in the biliary ducts are composed almost entirely of cholesterol and bile pigments with scarcely a trace of calcium. This is in sharp contrast to the stones that form in the gallbladder, in which calcium carbonate is commonly present in varying amounts.

Symptomatic relief is usually more pronounced when the gallbladder with stones is removed because in this case it is much more probable that the gallbladder was the original cause of the distress. In many cases, so-called functional intestinal distress or hyperirritability of the colon may quite accurately mimic the symptoms of classic gallbladder disease, and of course these symptoms then persist after the removal of the gallbladder.

The syndrome of biliary dyskinesia is not clearly defined, but it is quite possible that subjective symptoms might be produced by disturbance in the motility of the gallbladder or of the common duct and the sphincter of Oddi, in the absence of stones. The removal of such a gallbladder would clearly not give the relief that is commonly obtained in the presence of cholelithiasis. It is probable that, in most cases in which symptomatic relief is not obtained following cholecystectomy in the absence of gallstones or evidence of cholecystitis, the diagnosis is wrong.

CHORDOTOMY FOR PAIN

To the Editor:—For painful stump of an amputated thigh a patient was given paraspinal injection, presumably of alcohol. This was made at the third or second lumbar vertebra. The pain in the stump was almost entirely relieved, but in its place there are severe paroxysms of stabbing pain originating at the twelfth thoracic vertebra and radiating along the border of the last rib on both sides. Their severity demands constant sedation with opiates. Will you kindly inform me of the results of laminectomy and of chordotomy, or tell me where I can find these results summarized.

H. A. Hoskell, M.D., Windsor, Calif.

ANSWER.—Properly done by one experienced in procedures of neurologic surgery, chordotomy should completely relieve the patient of the pain. A small laminectomy should be done and a chordotomy performed at least four cord segments above the highest segment of pain distribution. With bilateral section of the pain-conducting pathways, between the dentate ligaments and the anterior roots, there will be a loss of pain and temperature sensibility below the level of the section but touch, pressure, position and vibratory sensibilities will not be impaired. The knife should pass completely through the white matter, between the landmarks named and well into the gray matter of the cord. With a careful operation, avoidance of hemorrhage around or in the cord and proper closure of the dura mater and muscles, there should be no loss of sphincter control or any motor weakness. In such a case chordotomy is no doubt preferable to posterior rhizotomy.

RHEUMATIC FEVER AND APHONIA

To the Editor:—A 4 year old girl has acute rheumatic fever of ten days' duration. She has received methyl salicylate externally and sodium salicylate internally in 5 grain (0.3 Gm.) doses four times a day, which has produced mild gastric symptoms and ringing in the ears when increased to five times a day. A slight but definite aphonia and some difficulty in swallowing has developed, the vagus being probably involved. There is no evidence of cardiac involvement other than rapid pulse. It would be greatly appreciated if you could suggest any therapy other than what is being given for the general condition and likewise any suggestions as to the mechanism of the vagus involvement and its treatment.

Charles H. Morhouse, M.D., Mitchelfield, L. I., N. Y.

ANSWER.—None of several authorities consulted have noted aphonia as a complication of rheumatic fever. In the presence of aphonia a reconsideration of the diagnosis may be in order; perhaps rheumatic fever exists coincidentally with some other condition that causes aphonia. Although salicylates in toxic doses may produce a number of neurologic symptoms, aphonia was not included in the list of Hanzlik (1927). Assuming that rheumatic fever with a related aphonia is present, the latter may be due to some local involvement and not necessarily to a disturbance of the vagus, or other cranial nerves may be responsible. Laryngitis occasionally occurs early in the course of rheumatic fever. Rheumatic nodules of microscopic size have been found in almost every tissue of the body. Occasionally, discrete nodules appear on the vocal cords. A serious and rare complication may be an acute diffuse edema of the epiglottis and vocal cords, which at times results in obstructive dyspnea. Aphonia may result from auricular enlargement or, assuming that no other central nerves are involved, one might think of a central (vascular embolic) lesion affecting the nucleus of the vagus nerve in the medulla; but this would necessitate the presence of frank endocarditis. In chorea, which is frequently associated with rheumatic fever, lesions of blood vessels and focal areas of encephalitis may occur. The data given by the correspondent are insufficient for one to make further conjectures as to the diagnosis.

If salicylates are not well tolerated when administered orally, they can be given in water by rectum 10 grains to the ounce

(0.65 Gm. in 30 cc.) or in a weak solution of starch. If salicylates are not effective in controlling fever and the articular disease, aminopyrine may be effective. A complete review of the current methods of treatment of rheumatic fever can be found in the Fifth Rheumatism Review (*Ann. Int. Med.* 12:1005 [Jan.] 1939).

DILUTION TEST OF KIDNEY FUNCTION

To the Editor:—Kindly give me the details of the kidney function test which eight glasses of water are given. Also the interpretation of the test.

C. G. Bower, M.D., Galesburg, Ill.

ANSWER.—In carrying out the dilution test for kidney function, according to Volhard's technic, the patient empties the bladder on arising and then drinks eight glasses (1,500 cc.) of water or weak tea in the course of from thirty to forty five minutes. He must remain in bed during the test period of three or four hours and refrain from food or drink. He is asked to urinate every half hour, keeping each urine in a separate container. The volume and specific gravity of the individual urines are measured. Normally, excretion of the ingested fluid is complete within two or three hours, at the most in four hours. More important as an index of normal renal function is the variation in the volume and specific gravity of the half hour urines. The largest half hour output may reach from 500 to 1,000 cc. (1 pint to 1 quart), with the specific gravity as low as 1.001. With impairment of renal function the first change is the reduction of the maximum half hour output and failure of a sharp fall in the specific gravity. Later the total four hour volume falls below the intake of fluid, and finally, the half hour samples become small and uniform both in volume and in specific gravity.

While the test is exceedingly simple, interpretation may be difficult in the case of an abnormal outcome, because the response of the body to a single large volume of water is determined by extrarenal as well as by renal factors. Thus, in the presence of cardiac or renal edema and even when there is only a tendency to edema, as in early cardiac failure and in the later months of pregnancy, much of the ingested fluid may be retained although there may still be considerable variation in the half hour urines. Any form of dehydration preceding the dilution test may seriously disturb the results. Thus fever, diarrhea, excessive perspiration and other conditions must be taken into account. The amount of salt in the diet on the day preceding the test may also affect the excretion of the water given. In most cases it becomes necessary to carry out a concentration test in order to obtain a reliable measure of renal function. It is evident that the dilution test may be a dangerous procedure in cases of increasing cardiac failure and pulmonary congestion or with severe hypertension and symptoms of encephalopathy, or in acute nephritis with oliguria and progressive edema. On the whole, the dilution test is not reliable and should be supplanted by the concentration test.

PROLONGED CARDIAC INVALIDISM IN CHILDREN

To the Editor:—I would appreciate your advice and your listing at schools, if any, for a boy aged 16 with rheumatic heart disease who is mentally alert but rebels daily that he cannot work. The condition of his heart is poor. At present he is in bed with rheumatic fever. His parents, not too wealthy, are willing to do anything to alleviate his boredom. I suggested a cardiac school, but I don't know whether there are any, and, if there are, where they are. Thank you for any help you can give me. The boy lives in Vermont.

M.D., Lynn, Mass.

ANSWER.—One of the difficult problems that has faced those treating prolonged rheumatic infections in childhood has been to maintain the morale and relieve the boredom of the children who have to stay in bed for months or even years.

There are certain hospitals where such children are well cared for over periods of time with an excellent environment and attention to the medical needs of the child. During convalescence recreational therapy and occupational therapy are instituted, but it is not necessary for children to be in such hospitals. They can be adequately taken care of at home if there is an understanding of their needs. The pioneer work of Miss Edith Terry and her associates at the Children's Heart Clinic of the Massachusetts General Hospital (with the help of the Committee for the Home Care of Children with Heart Disease) has resulted in the development of great advances in this field. Information can be obtained from her about the measures which she has introduced.

Among such measures are the establishment of the "In Bed Club" with its magazine, its jacket, its badge and other attri-

butes. Miss Love, who is one of Miss Terry's associates, has become expert in developing the use of the leisure time when the children are not too sick. Although care must be exercised as to the amount of activity of the children in bed in relation to the severity of their acute illness, it is even possible for them while still in bed to earn funds for their family, especially helpful if other members of the family are out of work.

URINARY INCONTINENCE AFTER PROSTATECTOMY

To the Editor:—A white man aged 73 had a transurethral prostatectomy in October 1938. Since then his general condition has been good, except for a generalized arteriosclerosis. Follow-up examinations in the hospital seem to show normal progress. However, a postoperative incontinence developed with a highly alkaline urine. Acidifying agents have failed so far to render the urine acid. The patient has been compelled to wear a urinal, but during the day only. At night he does not wet his bed, even though he is not wearing the urinal. The output during the night (12 midnight to about 9 a.m.) has been much higher than during the day. There is no infection. Since androgenic substance has been found valuable in the treatment of prostatic hypertrophy I should like to know whether it would be of help in correcting the incontinence also. Exercising the sphincter having been suggested already, what else can be done?

M.D., New York.

ANSWER.—The history given indicates that there is probably a urea-splitting organism in the urinary tract. As this contaminant is probably responsible for considerable bladder irritability attention should first be given to its eradication. Since it is almost impossible to acidify the urine in the face of this group of organisms the drug of choice is sulfanilamide, as its best action is in urine of alkaline reaction. Frequently, however, such patients become afflicted with alkaline encrustations on the operative site, which may necessitate instrumental removal either transurethrally or by means of cystostomy. In any event, diagnostic cystoscopy and a gram stain of the centrifuged specimen of urine, or even cultures of the urine, are indicated.

Although many claims have been advanced for androgenic substance it is doubtful if treatment of postoperative incontinence with this agent has ever been successful. However, if the patient does not have hypertension, ephedrine in three-eighths grain (0.024 Gm.) doses once or twice a day may be effective in stimulating the sphincter. Other agents of this type are strychnine in small doses ($\frac{1}{320}$ grain [0.00054 Gm.]) and benzedrine sulfate. Of course it is necessary to calibrate the urethra so that it will accommodate at least a 24F catheter, as strictures are frequent following transurethral resections and may be productive of incontinence. Exercising the sphincter is of definite value. If all of these means are of no avail it may be more convenient for the patient to use a Cunningham clamp than the more cumbersome urinal.

THROMBOSIS OF AXILLARY OR SUBCLAVIAN VEINS

To the Editor:—A man aged 54 sustained a contusion on the left upper arm. Five days later the basilic vein was enlarged and ropelike throughout its entire course. A few days later the entire left arm was cyanotic and swollen, especially the upper arm and hand. The cephalic vein was enlarged and varicose and the veins on the anterior surface of the chest were also enlarged. After eight weeks of complete rest in bed the basilic vein became normal, but the entire left arm and hand are still generally enlarged and slightly cyanotic, especially when held in a dependent position. The cephalic vein is still enlarged and varicose and the veins on the chest, while less pronounced, are still enlarged. From the symptoms, it appears that the thrombosis has extended to and involved the axillary or subclavian vein. The patient has been given increasing doses of potassium iodide and is now permitted to use the left arm for light duty. As the original injury occurred four months ago, what should be the prognosis and what treatment should be prescribed? May the moderate use of alcohol and tobacco be permitted?

M.D., Missouri.

ANSWER.—The description of the case permits the diagnosis of a thrombosis of the axillary or possibly subclavian vein with the characteristic collateral circulation on the chest wall and an increase of venous pressure in the superficial veins of the arm. It would be advisable to determine the location of the venous obstruction by an intravenous injection of an opaque, iodine-containing solution such as neo-iodipax or hippuran. A block of the sympathetic fibers going to the arm might be done to see how much of the swelling and cyanosis is due to a reflex vasoconstriction maintained by the thrombosed venous segment. By far the most satisfactory treatment is the resection of the occluded vein, which is most often exposed by a subclavicular, transpectoral incision. Relief from edema and cyanosis may occur spontaneously, but the process is unpredictable and may end up in severe neuralgia on exercise, a type of intermittent claudication.

It is doubtful whether the moderate use of alcohol and tobacco would influence this condition.

ASTHMA AND MENSTRUATION

To the Editor:—A white woman aged 36 has had allergic asthma since the onset of menstruation at the age of 12. In the beginning it would trouble her only for a few days before the menstrual period but now it is present in mild form (easily controlled by symptomatic treatment) throughout the cycle but becomes almost intractable a few days before the period and is relieved only with the onset of bleeding. She is the mother of six children, the youngest 2 years of age. Each pregnancy has resulted in complete remission of all asthmatic attacks after the first one to three months. She has had no miscarriages or abortions. General physical examination, including a check of the sinuses, a blood count, a Wassermann test and urinalysis, revealed no significant indications except for a moderately emphysematous chest. Pelvic examination was not remarkable. The sputum during attacks shows abundant eosinophils, and differential counts done at these times have shown moderate (from 6 to 10 per cent) eosinophilia. She will not submit to skin testing. The patient has arranged to make the bedroom as nearly dust free as possible and has been an elimination diets but has not been benefited. I have treated her now for one year on theophylline with ethylene diamine by mouth up to 15 grains (1 Gm.) in twenty-four hours and occasional doses of epinephrine 3 minims (0.2 cc.), which gives good symptomatic control in the intramenstrual period—much better than larger and more frequent dosage of epinephrine without theophylline with ethylene diamine or with ephedrine and phenobarbital compounds had previously done. The premenstrual attacks are, however, becoming more severe. Intravenous theophylline with ethylene diamine ($7\frac{1}{2}$ grains [0.5 Gm.]) with 30 cc. of 50 per cent dextrose, frequent epinephrine, rare doses of morphine and sodium pentobarbital up to 3 grains (0.2 Gm.) see her through this hectic period. On several occasions she has seemed practically moribund. It has been noted by the patient that any febrile state was followed by a period of partial or complete remission of symptoms. Fearing to use any kind of fever therapy at my disposal except autogenous blood, I have on two occasions induced mild fever (102 F.) by repeated injections of her blood intramuscularly. This empirical treatment has resulted in temporary improvement. The questions I now wish to ask are: 1. What would be the result of x-ray castration? Would such a procedure be justified? 2. Have you any confidence in endocrine therapy? If so, what? (This has been suggested by a consultant.) 3. Have you any additional suggestions as to symptomatic treatment? Would you advise the trial of epinephrine in oil in place of regular 1:1,000 epinephrine?

R. E. Shaw, M.D., Clarksville, Iowa.

ANSWER.—This query brings up two important considerations in the treatment of bronchial asthma. In the first place the phrase "she will not submit to skin testing" is unthinkable in this day and age. There has been a great improvement in the making and in the interpretation of skin tests. It is not an ordeal, as implied. The tests are painless if done cutaneously, and if carried out intracutaneously the pain is slight. No after-effects should follow skin testing but the testing should be carried out by one who has had experience and who can make all the necessary tests, both cutaneous and intracutaneous. In a patient who is only 36 the substance or substances which cause the asthmatic attacks should be discovered, especially since eosinophilia is present. The patient should be persuaded to have these tests done.

The relationship of bronchial asthma to menstruation and pregnancy has received a great deal of consideration and the consensus is that there is a definite connection. But no one has been able to prove that menstruation is the underlying cause of asthma. One must realize that menstruation is merely a predisposing factor in asthma; there is usually a hereditary factor and the attacks are precipitated by exposure to some such substance as pollen, molds, house dust, drugs or certain food. Every one agrees that many female asthmatic patients are worse just before the flow and feel better as soon as menstruation begins. Because of this, many physicians give injections or tablets of ovarian material. Injections once a week of an extract of the whole ovary are probably most commonly used, and in many cases excellent results are obtained; the amount of asthma is frequently much lessened by its use.

X-Ray castration for asthma is not warranted, especially for a patient so young. Artificial menopause is sometimes followed by intractable asthma. Epinephrine in oil intramuscularly gives longer relief than 1:1,000 epinephrine subcutaneously.

PUSTULAR PSORIASIS OF HEEL

To the Editor:—Is there such a condition as "pustular psoriasis of the heels?" The patient has shown no other signs of psoriasis since the onset of the condition of his heels two years ago. There is hyperkeratosis with associated pustulation of the heels in which the new pustules persist for several days and then are apparently absorbed but with further resultant exfoliation of the overlying layers of the skin. Therapy has included roentgen and ultraviolet radiation and all sorts of fungicides. Constitutional therapy has not been neglected. Improvement seems to proceed to a certain point and then the condition either gets worse, if neglected, or remains stationary, if treatment is continued.

M.D., Virginia.

ANSWER.—Pustular psoriasis occurs on the palms and soles and may be associated at times with ordinary psoriatic patches elsewhere on the skin. The lesions are characterized by exfoliation and insets of intra-epidermic lakes of sterile pus. It needs to be differentiated from eczematoid ringworm and acroderma-

itis perstans of Hallopeau. The relationship to so-called pustular bacterid is much debated. Some dermatologists believe that pustular psoriasis, acrodermatitis perstans and pustular bacterid are mere variants of one another clinically and histologically. In its most characteristic form, however, pustular psoriasis may be differentiated from acrodermatitis perstans of the palm by the fact that in the former the lesions originate on the thenar and hypothenar surfaces, whereas in the latter they first involve the regions about the nails. In acrodermatitis there is atrophy, even of the phalanges, while in pustular psoriasis there is none. The pustules are sterile in pustular psoriasis, while they often contain staphylococci in acrodermatitis.

In pustular bacterid, which many believe is identical with pustular psoriasis, the best therapeutic responses have followed the eradication of foci of infection. These have been found most frequently in the tonsils and teeth. Stimulating agents applied locally often are found to irritate. In pustular psoriasis also one should on general principles seek foci of infection. If any are found they should of course be eradicated. Such general measures as are applicable for other types of psoriasis may be employed, such as the administration of arsenic. Pustular psoriasis resists ordinary local therapy. A combination of chrysarobin and ultraviolet radiation has been found useful. Roentgen therapy may be helpful. These remedies should not be used too long if they are ineffective, nor should their dosage go beyond a safe limit.

CHRONIC LETHARGIC ENCEPHALITIS

To the Editor:—A white man about 23 years of age had what he says was a mild case of scarlet fever and mumps about five years ago. Since that time he has been drowsy and lethargic, especially late in the day. He says that the condition is no worse now than it was four years ago, but he is more conscious of it and worries all the time. His wife states that he talks more slowly and does not smile as much or take an interest in his friends and surroundings. He refuses to go out with other people, as he is afraid they will notice his trouble. The only other complaint is shortness of breath. Physical examination is essentially negative. He is well developed. The tonsils are hypertrophic. The facial expression is rather blank; however, he does appreciate a good joke. The superficial reflexes are somewhat hyperactive. No pathologic reflexes are present. I have termed this encephalitis with a slight tendency toward paralysis agita. As to treatment, I am using benzedrine sulfate. The questions in my mind are: Is the benzedrine a curative measure or does it only give symptomatic relief? In view of the fact that the patient has gone four years without getting any worse, is there any chance of complete recovery? Would hospitalization with studies of spinal fluid and x-ray examination of the skull be of any advantage? I am allowing the patient to continue his work; would bed rest be better? Is it better to use stramonium with the benzedrine?

J. F. Hattenbach, M.D., Cleveland.

ANSWER.—Benzedrine sulfate is used for symptomatic relief only if the patient has encephalitis. The chronic lethargic encephalitis due to influenza is usually an incurable affliction. Occasionally patients are seen whose symptoms are mild and who under proper medication improve so much that it appears that the patient has made a recovery. The pathology of encephalitis due to influenza, on the one hand, is such as not to permit recovery. Encephalitis following scarlet fever and mumps, on the other hand, usually clears up completely. Spinal fluid examination should be made. It may show evidence of abnormalities in the cell count, globulin content and colloidal gold reaction. The pressure of the fluid should be determined by a manometer with testing for subarachnoid block. The patient should work if possible. It is suggested that he be given 30 drops of tincture of stramonium three times daily for one week, then 50 drops three times daily for another week and 75 drops three times daily from then on; 10 mg. of benzedrine sulfate should be given in the morning and at noon. No benzedrine should be given after 3 p. m. because of its tendency to produce insomnia.

EXOPHTHALMOS AFTER THYROIDECTOMY

To the Editor:—Can you give me some information on the treatment of exophthalmos which follows thyroidectomy for acute exophthalmic goiter? Following the operation there was only a slight protrusion of the eyes, but approximately six months later the left eye became extremely prominent and the right eye a little more than at first. This exophthalmos is severe. The patient has a —12 basal metabolic rate. I am interested in knowing whether or not the administration of thyroid or any other therapeutic agent is of any value in this type of case or whether surgery offers the only possibility of relief.

M.D., N. Y.

ANSWER.—Sometimes exophthalmos of the type described is relieved by the administration of iodine. This may cause the basal metabolic rate to be reduced to a lower level, with symptoms of hypothyroidism. It may therefore be necessary to give both iodine and thyroid. This is the only hope of relieving the condition medically. Surgical procedures should not be resorted to unless the exophthalmos is so pronounced that prolapse of the eyeball or corneal ulcers occur.

IMMUNITY TO TETANUS

To the Editor:—Will you please send me any information on record as to whether or not recovery from a tetanus infection will confer permanent immunity.

Ralph E. White, M.D., Santa Ana, Calif.

ANSWER.—The question cannot be answered until such a patient has been followed over a period of years with tests of the blood serum for amounts of tetanic antitoxin persisting. There is every reason to believe however that, if a person has once had an attack of tetanus and has recovered, response to a second infection would be more prompt and effective. The anamnestic antibody response is a well known phenomenon and has been shown to apply to reinjections of tetanus toxoid. Practically, however, if the antitoxic content of the serum is not known, prophylactic injection of tetanic antiserum is the only safe procedure in any condition in which tetanus is likely to develop.

POSSIBLE CONGENITAL SYPHILIS

To the Editor:—A woman aged 28 was treated throughout her pregnancy intensively with neorsphenamine and a bismuth compound. At term her Wassermann reaction was 4 plus, but she gave birth to an apparently normal child with a negative Wassermann reaction. Should this child receive antisyphilitic treatment, and if so at what age and in what amount? Another case is exactly the same except that the second child has a positive Wassermann reaction. What treatment would you advise in this case and at what age?

M.D., New York.

ANSWER.—The information given in regard to the first baby is inadequate. If the blood serologic studies were done within eight weeks after the baby's birth, the report is not entirely reliable as to the presence of syphilis in the child. However, if subsequent serologic tests have shown the child's blood to be negative and if the baby has no clinical evidence of syphilis there is no need of treatment for syphilis. Each month after the second month of life that the serologic tests are reported negative, the greater becomes the probability that the child does not have syphilis. Accordingly, if the child is now more than 2 months old and the tests are negative there is no need of treatment for syphilis. Continued observation and reexamination for syphilis until the child is at least 2 years of age are, however, advisable.

If the time factors have been given the same consideration in the second case as in the first, the second child should be treated for syphilis immediately. If the positive test was taken when the child was more than 2 months old, treatment is indicated. If, however, the blood was taken from the umbilical cord or during the first month of life, the test is in reality a test of the mother and not the child, because the substance which produces a positive Wassermann reaction may have been carried over to the child, which would not produce syphilis. On the other hand, if *Spirochaeta pallida* as well as the substance x was transmitted, the child will develop syphilis. In the interpretation of the serologic tests in the newborn the time factors are most important, and they were not stated in either of these cases. If the second child has syphilis, treatment should be started immediately. The method and manner of treating a newborn child for syphilis has been outlined in a recent publication of the Cooperative Clinical Group and may be obtained from the Venereal Disease Division of the United States Public Health Service, Washington, D. C.

FLEISCHMANN'S YEAST—ALLERGENS IN RICE

To the Editor:—In the two recipe books for allergic patients which have been published recently I find conflicting statements with regard to Fleischmann's yeast: One says that the product is made of tapioca and the other says that it is made of wheat. Each book claims to quote the makers. Can you tell me which of these is correct? Can you tell me whether wild rice contains the same allergen as polished or brown rice?

M.D., Illinois.

ANSWER.—Both recipe books are partly correct. The label for Fleischmann's yeast states that the product is fresh yeast with cereal or tapioca flour, and it is probable that the product contains either ingredient depending on market conditions.

Wild rice is a species of rice found in Canada, in the United States and in other parts of the world. Wild rice belongs to the genus *Zizania*, while the common brown rice belongs to the genus *Oryza*. Although it is a different genus, it belongs with common or brown rice in the family of Gramineae or grasses. It is difficult to say whether it has the same allergen, but it undoubtedly behaves as do other members of the Gramineae. In other words, it is likely to have an antigen common for the Gramineae in addition to an antigen which is specific for the genus or species. Generally speaking, the relationship is close enough so that it would not be advisable to substitute one for the other in case of allergy to one of these rices.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, October 14, page 1511.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Feb. 12-14. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. *Written*. Part I. Various places throughout the United States and Canada, Feb. 15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Orol*. Philadelphia, Nov. 3-4. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written*. Various sections of the United States, Feb. 19. Formal application must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination and review of case histories (Part I) for Group B candidates will be held in various cities of the United States and Canada, Jan. 6. The final date for receipt of these applications was Oct. 4, 1939. General orol and pathologic examinations (Part II) for all candidates (Groups A and B) will be conducted in Atlantic City, N. J., June 8-11. Applications for admission to Group A, Part II examinations must be on file not later than March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).*

AMERICAN BOARD OF OPHTHALMOLOGY: *Written*. Various cities of the United States and Canada, March 9. Oral. New York, June 10. Formal applications must be received before Jan. 1. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Boston, Jan. 20-21. Applications must be filed on or before Nov. 1. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF PATHOLOGY: Memphis, Nov. 22-23. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: New York, April 30 and May 1. Kansas City, Mo., preceding the Region III meeting of the American Academy of Pediatrics, Seattle, June 2. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, December. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlanta, Ga., Dec. 9-11. Sec., Dr. Byrl R. Kirklin, 102-110 Second Avenue S.W., Rochester, Minnesota.

AMERICAN BOARD OF SURGERY: Part II. Atlanta, Ga., Nov. 15. *Will include candidates living in the South only.* Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: Chicago, Feb. 9-11. (The only examination session to be held in 1940.) *Case reports must be submitted not later than November 9.* Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Maryland June Examination

Dr. John T. O'Mara, secretary, Board of Medical Examiners of Maryland, reports the written examination held at Baltimore, June 20-23, 1939. The examination covered nine subjects and included ninety questions. An average of 75 per cent was required to pass. One hundred and fifty-two candidates were examined, of whom 145 passed and seven failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1939)		83.3

Louisiana June Report

Dr. Roy B. Harrison, secretary, Louisiana State Board of Medical Examiners, reports the written examination held at New Orleans, June 1-3, 1939. The examination covered twelve subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and forty-three candidates were examined, all of whom passed. Seven physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Northwestern University Medical School.....	(1939)		83.6

Book Notices

New and Nonofficial Remedies, 1939. Containing Descriptions of the Articles Which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1939. Cloth. Price, \$1.50. Pp. 617. Chicago: American Medical Association, 1939.

New and Nonofficial Remedies is of interest and value to many classes of persons who are concerned with the use of medicinal preparations—physicians, pharmaceutical manufacturers, chemists, pharmacologists, government officials, teachers, medical students and ultimately the lay consumer, in whose interest that of all must be judged.

To the physician the book is a reliable source of therapeutic and posologic information on the newer *materia medica*. To the pharmaceutical manufacturer it represents a record of the best achievement in his field and a goal toward which he may bend his efforts in improving his own ends. To the chemist it is a book of standards. To the pharmacologist it represents a compendium of knowledge of the newer drugs. To the government official it represents a book of standards for preparations which have not become official and a yardstick on permissible therapeutic claims made for new products of proved or promised therapeutic value. To the teacher it is such a text on progressive modern *materia medica* as is nowhere else available. To the medical student it is a valuable source of training in rational therapeutics, a *vade mecum* for his subsequent professional career. To the lay consumer it is a valuable protection that operates indirectly through his physician. Criticisms of the form and manner of presentation of data in this book have been made with justification from the points of view of the various classes enumerated. The fact remains, however, that each can find in it what he looks for if he will take the trouble to use the paraphernalia provided.

New and Nonofficial Remedies 1939 conforms to the general pattern of the thirty-two annual volumes which have preceded it. Some new drugs have been added, a great many new dosage forms of already accepted drugs have been added, some drugs have been omitted either for conflict with the rules or because they have been taken off the market. Most noteworthy among the newly accepted drugs are the crystallized estrogenic preparations Estrone (theelin) and Estriol (theefol). In line also with the modern trend toward the use of crystalline principles instead of extractive preparations are the new crystalline vitamin principles Thiamin Chloride (crystalline vitamin B₁ hydrochloride), Nicotinic Acid (vitamin B₂) and Nicotinic Acid Amide. Other newly included drugs are Benzedrine Sulfate, Prostigmine (as the bromide and methylsulfate) and Immune Globulin (Human).

Noteworthy omissions are those of serobacterins, because of failure to live up to their promise of therapeutic value, and "Suppositories Salyrgan", found to be the cause of undesirable irritation.

The chapter formerly called Organs of Animals has been dispersed and the various endocrine preparations formerly included in this chapter appear alphabetically under their individual names: Ovary, Pancreas, Parathyroid, Pituitary and Thyroid. Drastic revision of the monograph Ovary was made necessary by the addition of new crystalline principles.

The chapter Vitamins and Vitamin Preparations has been revised to use the newer chemical nomenclature to present the "Allowable Claims" up to date. Other revisions are found in the articles Anesthetics Local, Bismuth Compounds and Fibrin Ferments and Thromboplastic Substances.

Dissociation of Tubercle Bacilli: Investigations on the Mammalian Types Including BCG. By J. Frimodt-Møller. *Acta tuberculosa Scandinavica*, Supplementum II. Paper. Pp. 256, with 49 illustrations. Copenhagen: Einar Munksgaard, 1939.

This extensive monograph in English on the dissociation of tubercle bacilli, presented to the University of Copenhagen in fulfillment of the requirements for the degree of doctor of medicine, also appears in the *Acta tuberculosa Scandinavica*. It is a laudable volume from the standpoint of reviewing ably a subject which has been controversial from its explosive inception about a decade ago. The author reports on part of extensive investigations (reported in 1932 and 1935) carried out in the tuberculosis department of the State Serum Institute at

Copenhagen on matters relating to the types of tubercle bacilli. The purpose at hand was to study the variations of bovine and human strains isolated from tuberculous material from human beings and cultivated on artificial nutrient mediums and to examine any possible changes of their virulence. It was beyond the scope of the work to describe strains which displayed variations solely as a result of animal passages. These investigations having proved to be closely related to studies on variations in the growth of tubercle bacilli carried out by other workers, it was natural to include tests of their results and methods and to supplement them with dissociation experiments on the BCG strain. A possible justified criticism might be offered that this is not an original investigation but a repetition or verification study in which no newly devised methods are used with a view to advancing the horizon of knowledge on this subject. Thus also the conclusions give little new information for so extensively recorded an investigation. However, many will welcome this book for its rounded presentation of the previous investigations on dissociation (chapter II) and further attempts to dissociate BCG (chapter III). Besides dissociation, generally understood to mean variation in the structure of bacterial colonies, which variation may be associated with a change in virulence (a term first employed by Petroff in 1927), the author utilizes the Royal British Commission on Tuberculosis terminology of 1907 in which a convenient term for the greater or lesser facility with which a tubercle bacillus grows on artificial nutrient mediums was introduced, the words dysgonic and eugonic meaning respectively a sparse and a vigorous growth.

The chief impression gained by the author when looking back on the investigations reviewed is the great multiplicity of observations, which however in only few cases will bear close examination. Thus it seems justifiable to report a series of experiments in which it has been possible, according to the author, with a simple technique to reproduce dissociations with strains of both human and bovine types. In addition, experiments on the dissociation of the BCG strain are included. Chapters VI to XII are taken up with a consideration of the author's investigations, and an appraisal and summary are included in chapters XIII and XV, with an appendix of experimental records. The points made in the summary are that pure cultures of both the dysgonic and the eugonic colonies of human tubercle bacilli could be preserved for an unlimited period through any number of transplantations or animal passages, and the two variants had the same virulence for guinea pigs and rabbits as the standard human type, with no mutual differences. The bovine dissociants were in many cases mutually different in their growth, the dysgonic colonies being smooth, dome shaped and bright and the eugonic colonies irregular, finely wrinkled and dry. Rough eugonic Petroff medium colonies contained fewer viable bacilli than dysgonic colonies, a fact which must be considered when appraising virulence. An acid Löwenstein medium stimulates the formation of eugonic secondary colonies (R forms), as stated by previous investigators. The factor inciting this was not determined. It cannot be said that it is merely caused by adaptation to glycerin or by increased resistance acquired through lysis. The dissociations always took place in the direction from dysgonic to eugonic forms (S, smooth, to R, rough). The bearing of dissociation on the relationship between the human and the bovine type is debated, but so far no transformation in vitro of a bovine to a human type has been demonstrated. Repetition of Petroff's experiment on forced dissociation of BCG by means of cultivation on Sauton with rabbit immune serum proved to be negative, no change being found in the mode of growth or the virulence of the BCG strain. Reservation is being taken in respect to Petroff's claim of having demonstrated virulent forms of BCG cultures; nevertheless, though practically minimal, the possibility is entertained theoretically since BCG-like variants were found to arise from typical dysgonic bovine strains, and avirulent eugonic variants actually regained their virulence by animal passages. The dissociation of H 37 was substantiated, however, only on the assumption that H 37 was originally bovine and not of human type (which is contrary to all the published data on H 37).

The monograph is well worth reading, especially for its rounding out of a subject which still requires further solution and possibly to be attacked by more exacting and conclusive methods. It may possibly resolve itself when dissociation as a

whole is more fully understood. This has happened before in tuberculosis with the acquisition of additional knowledge, after which a few well planned experiments have been able to settle a problem. However, since the specialist and investigator must be aware of the problems involved in the present interpretation of tuberculosis, this volume should be accepted heartily by those wishing to be conversant with the subject of the dissociation of tubercle bacilli and how this affects the status of BCG today. It is presented in good form and in a clear, well written English. The cost is nominal.

Medical Jurisprudence and Toxicology. By William D. McNally, A.B., M.D., Assistant Professor of Medicine and Lecturer in Toxicology, Rush Medical College, University of Chicago, Chicago. Cloth. Price, \$3.75. Pp. 386, with 23 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

The purpose of this book, as stated in the preface, is to provide medical, pharmaceutical and dental students with a textbook covering the essentials of toxicology and also to furnish physicians with information concerning medicolegal testimony. Seven eighths of the book is composed of material on poisoning, blood, semen and hairs, all of which has been abridged from the author's larger work on toxicology published in 1937; 263 pages of this section is devoted to a discussion of poisoning in its various forms: homicidal, suicidal, accidental and industrial. Major emphasis is placed on clinical aspects such as methods of diagnosis and adequate treatment of various poisonings. One eighth of the book represents newly written chapters on courts, sudden or violent death, firearms identification and insanity. The treatment of these phases is rather superficial.

Although modestly concealed by the author, drama stalks throughout the pages of the book. Drawing on his wide court experience as expert toxicologist in *causes célèbres* of the past quarter century, the author regales his reader with accounts of mass murder by arsenic for the purpose of collecting insurance (p. 169), the application of geometry as well as chemistry in exposing a "framed" cyanide murder (Orpet case, p. 267), the attempted murder of an archbishop, his friends and associates by putting poison in the soup served at a banquet in the prelate's honor (p. 171), and even the detection of hydrocyanic acid in the blood of one of the victims of the Cleveland Clinic disaster (p. 266).

Apparently the process of condensing from the older and more voluminous text was conducted largely by the "scissors and paste-pot" method. Paragraphs and pages were lifted from the older book with the result that in this volume transitions are oftentimes abrupt, owing to the elimination of intervening material. Unfortunately this material was largely copied verbatim, including mistakes and typographic errors, so that a student who attempts to follow up the author's references will be required to do some careful detective work. The literature of toxicology has become so extensive that it is impossible to cover the entire field in any moderate sized volume. For this reason the author may be pardoned for the many omissions. While this book is a fairly satisfactory elementary textbook, it is unfortunate that the author and publisher did not use greater care in providing a more accurate and reliable work for student and reference use.

Traité d'ophtalmologie. Publié sous les auspices de la Société française d'ophtalmologie. Par MM. P. Baillart, Ch. Coutela, E. Redslob, E. Velter. René Onfray: Secrétaire général. Tome II: Physiologie, techniques d'examen. Par MM. P. Baillart et al. Cloth. Pp. 1,144, with illustrations. Paris: Masson & Cie, 1939.

This is the second volume of the new eight volume encyclopedia of ophthalmology that is being produced under the auspices of the French Society of Ophthalmology. It is divided into two parts, physiology and technic, with the following subdivisions: the protective apparatus of the eye, by Magitot and Rossano of Paris; sensibility of the eyeball, by Cerise and Thurol of Paris; nutrition and circulation of the eye, by Baillart of Paris; conjunctival circulation, by Rollin of Paris; endocular fluids and nutrition, by Magitot of Paris; ocular tension by Magitot; physiology of extrinsic ocular motility, by Nordman of Strasbourg; intrinsic musculature, by Magitot; theoretical and applied optics, by Haas of Paris; physiologic optics, by Joseph of Paris; biologic optics, by Léplat of Liège; entopic phenomena by Viallefond of Montpellier; changes in the retina under the influence of light, by Magitot; physiology of vision,

by Piéron of the Collège de France, and binocular and spatial vision, by Opín of Toulon. The chapters on the technic of examination are shorter and divided in the following manner: methods of examination of the living eye, by Lemoine and Valois of Never; optotypes, by Lemoine and Valois; trial cases, by Joseph of Paris; instruments for the measurement of refraction, by Haas of Paris; skiascopy, by Joseph of Paris; perimetry, by Dubois-Poulsen of Paris; tonometry, by Dubar of Paris; ophthalmodynamometry, by Rollin of Paris; methods of photography of the eye, by Mawas of Paris; radiology and radiography, by Hartmann of Paris; methods of localization of intra-ocular foreign bodies, by Dollfus of Paris, and electromagnets and sideroscopes, by Veil of Paris. The chapters are not of as uniform caliber as are those of the first volume. Some, particularly those of Magitot and Baillart, are brilliant but tend slightly toward the expression of personal opinion, whereas others are somewhat skimpy, especially the one on biomicroscopy. Isn't it interesting to see that term, coined by our own Edward Jackson, coming into such universal use? Striking is the lack of chauvinistic attitude throughout the chapters, for the bibliographies are international in character and full credit is given, regardless of differences in international politics. This is refreshing in contrast to the regimentative attitude that prevails elsewhere on the continent. The mechanical aspect of the volume is good and the majority of the illustrations are excellent. Particularly good are some of the color plates. After the second volume has been digested, the feeling still remains that this is a "must have" work.

A Textbook of Obstetrics with Special Reference to Nursing Care. By Charles B. Reed, M.D., F.A.C.S., Associate Professor of Obstetrics, Northwestern University Medical School, Chicago, and Bess I. Cooley, R.N., Supervisor and Instructor, Department of Obstetrics, Wesley Memorial Hospital, Chicago. Cloth. Price, \$3. Pp. 476, with 209 illustrations. St. Louis: C. V. Mosby Company, 1939.

The authors are a physician of many years' experience and a competent supervisor of nurses at an excellent hospital. There has been a tendency for textbooks on nursing gradually to broaden their subject matter until the content pertains more to the practice of medicine than to that of nursing. This book goes further in that direction than most. It contains several excellent chapters, particularly on anatomy and physiology. There is a good chapter on anesthesia and analgesia, and a good chapter on normal labor.

The arrangement is not always orderly; for example, the chapter on antepartum care digresses to give a description of aseptic technic to be observed during the birth of the child. This is undesirable and entirely out of place. There are a number of statistical facts, for example those of multiple pregnancy and those on intra-uterine mensuration of the fetus, which contain facts and formulas that could not be of value to the nurse. A paragraph concerning the thyroid gland states that, "in one series, 60 per cent of pregnant women were aborted because of glandular hypertrophy." No reference is given nor are there any references in the book. This statement on the thyroid gland would tend to give the student nurse an entirely erroneous conception concerning thyroid disease complicating pregnancy.

The chapter on toxemias might lead the nurse to infer that certain methods of treatment are mandatory rather than methods available to the physician. There is a statement about eclampsia but no discussion of preeclamptic toxemia. The chapter is poorly arranged. There is also the following statement concerning the treatment of eclampsia, which is not subscribed to by most obstetricians at the present time: "If the woman is in labor, the process should be hurried as much as possible by forceps or by version and extraction. If not in labor, the uterine activity can be induced by the bag, bougie, or possibly in an emergency by cesarean section under gas anesthesia."

In one chapter there is given a list of eight types of pain in ectopic pregnancy which, it is said, the nurse should know about. This might be confusing even to the trained obstetrician. Two of these types of pain could be elicited only by pelvic examination.

The authors write easily about the signs of vitamin E deficiency and the value of vitamin E for bleeding during pregnancy. While vitamin E appears to be of value in the prevention of spontaneous abortion, its description in this connection would be confusing to the student nurse.

The book contains descriptions of several methods which appear to be entirely obsolete and some of which are considered to be dangerous; for example, resuscitation of the asphyxiated baby by means of Byrd's method of manipulation.

In connection with the advice concerning intravenous transfusion, a description of the technic for cutting down on, and ligation of, the vein is given. This is a procedure which is almost obsolete, and yet there is nothing in the description to indicate that this is so. A description of the Walcher position is interposed between paragraphs on curettage for incomplete abortion and paragraphs on artificial interruption of pregnancy. A statement is made concerning artificial rupture of the membranes at term for placenta praevia centralis. Surely the authors must have had in mind placenta praevia partialis or marginalis. There is a description of the induction of labor by four doses of from 5 to 10 grains of quinine sulfate. It is suggested that the patients may be given a drachm of 1:80 dilution of chemically pure sulfuric acid in a glass of water for each 5 grains of quinine. Treatment which is rarely employed is out of place in a book on obstetrics for nurses. A description is given of the use of laminaria tents for the interruption of pregnancy. This method of induction of labor is not surely aseptic and there is no reason to include this in a textbook on obstetrics or on nursing. There are a number of excellent outlines for the setup of the operating rooms for various obstetric procedures which should be of considerable value to the graduate nurse, and particularly to one who is instructing nurses in obstetric procedures.

This book would have been of greater value if it had been published in condensed form as a handbook of the nursing technic of obstetric procedures.

Psychischer Befund und psychiatrische Diagnose. Von Professor Kurt Schneider, Direktor des Klinischen Instituts der Deutschen Forschungsanstalt für Psychiatrie (Kaiser Wilhelm-Institut) in München. Paper. Price, 1.40 marks. Pp. 27. Leipzig: Georg Thieme, 1939.

This is devoted to a discussion of symptoms and their evaluation in psychiatric diagnosis. It is intended primarily for practitioners. The subject is introduced with a suggestion that disturbances in the individual functions be sought for and interpreted and, from these symptoms, a diagnosis be built. The more frequent psychoses, schizophrenia and cyclothymia, and the demarcation of these psychoses from neuroses, psychopathic personality and toxic and organic cerebral conditions are stressed. Disorders of perception, of thought and mood and of will and instincts are considered. Symptoms are then grouped into those which are significant for a diagnosis of schizophrenia and those which are more general and can be utilized as diagnostic aids only against the background of the total clinical picture. Interspersed are warnings against pitfalls in the interpretation of symptoms and cautions as to common sources of errors. This all too brief monograph is a concentrate of an extensive psychiatric experience. A study of its pages will reward the prepared reader, yet one questions its usefulness for the general practitioner. The average physician, allergic to psychiatric phraseology, may find this condensed presentation, the delicate distinctions of ideas and categories and the terminology too formidable for ready usage.

Lungenabszess und Lungenabszedierungen im Kindesalter. Von Dr. med. Sotirios Roufogalis. Mit einem Geleitwort von Prof. Dr. med. F. Goebel, Direktor der Kinderklinik der Medizin. Akademie, Düsseldorf. Paper. Price, 16.50 marks. Pp. 166, with 37 illustrations. Leipzig: Johann Ambrosius Barth, 1939.

Pulmonary abscess in the opinion of Professor Goebel, who writes the introduction, has received little attention in the pediatric literature (German), which he notes is in marked contrast to the extensive consideration given the subject in the literature of surgery and internal medicine, and this literature is concerned largely with the disease as seen in the adult. The generally accepted causes of pulmonary abscess are considered impartially; in fact all through the monograph the author presents data and elaborates their bearings on the problems, with no attempt at emphasizing his own point of view, which is that of a pediatrician. Tonsillectomy is noted as a rather frequent cause of pulmonary abscess, though at one time it was thought to be a rare or, in Germany, a nonexistent etiologic factor in this disease. Diagnosis is chiefly by the x-rays, though the physical signs are clearly and carefully stated. In treatment

the author is conservative as to radical operation. He states that, whereas formerly preference was given to surgical intervention, today operation is seldom advised unless empyema is present. (The monograph concerns children only.) Though strongly conservative on the question of surgical intervention, the author feels that there are cases in which external operation should not be postponed, especially in older children. He regards it as extremely difficult to lay down rules as to the time to operate as well as to determine the right time in any particular case. In most cases the best results have come from general treatment by the pediatrician. He speaks well of bronchoscopic aspiration, but he has had limited opportunity for observing its effect in his own cases. The younger the child the worse the prognosis of pulmonary abscess, according to his experience. The illustrations are all reproductions of roentgenograms; they are well chosen and show clearly what they are intended to show. The statements are well documented by references and case reports. The general excellence of the book and the wealth of detail would justify a good index for ready reference. In common with similar monographs, this one has only a table of contents.

The Licensing of Professions in West Virginia. By Frances Priscilla De Lancy, Instructor in Political Science, West Virginia University, Morgantown, West Virginia. A Dissertation Submitted in Partial Fulfillment of the Requirements for the Degree of Doctor of Philosophy in the Graduate School of Arts and Sciences of Duke University. Cloth. Price, \$2.25. Pp. 197. Chicago, Illinois: Foundation Press, Inc., 1938.

Much has been said concerning the defects of our various systems of professional licensure, but little has been written about the fundamental principles or social theories on which such regulation must rest. In her doctoral thesis Miss De Lancy has analyzed the professional laws of West Virginia and summarized their history. For the purpose of her study she has formulated a definition of the term profession both interesting and unique, namely "that organized vocation in which individuals are licensed by the state after a period of formal academic education and training in an approved professional school." So restricted, the term excludes such long recognized professions as the ministry, journalism, teaching and the stage because they are not licensed by the state. It also ignores such newer aspirants to professional recognition as plumbers, realtors and barbers on the ground that for them no formal education is deemed necessary. In her discussion of the administration of licenses the author has shown unusual discrimination in the appraisal of the functions of professional associations. Unfortunately it is erroneously stated that Negro physicians are not admitted to membership in the American Medical Association. Altogether the book is stimulating and informative. An excellent bibliography enhances its value.

Schilddrüse, Jod und Kropf: Klinische und experimentelle Untersuchungen. Von Max Saegesser. Helvetica medica acta, Supplementum IV, 1939. Paper. Price, 10 Swiss francs. Pp. 163, with 20 illustrations. Basel: Benno Schwabe & Co., 1939.

According to the conclusion on page 162, the purpose of this book is goiter prophylaxis. With two exceptions (and two translations) only German literature is quoted. On page 94 the analyses on one sample of blood are given, in micrograms per hundred cubic centimeters (γ%), as from 8.2 to 69.2. With 750 per cent error it is rather difficult to understand how small differences in the results of iodine analysis can be used for theoretical work. Furthermore, there is a peculiar method of using the analyses. The micrograms per hundred grams (γ%) in thyroid, heart, lung, liver, kidney, muscle, brain, spleen and skin of a rat are added together and the total is found to be from 1,677 to 8,894 micrograms in the different experiments, and yet in one case the thyroid is said to contain only 721 micrograms. Just what these figures mean it is impossible from reading the entire book to determine, since the weight of no organs is given, and yet on the basis of these experiments the exact rates of iodine anabolism and catabolism are estimated. The alcohol-insoluble iodine in the blood is stated to be almost entirely in the corpuscles and it is concluded that this iodine in the corpuscles is what passes out in the urine, although in another place it is stated that the process of iodine catabolism has to be gone through with in order to make this iodine alcohol soluble. On page 101 it is stated that simply raying the skin with ultraviolet causes an increase in the iodine content of the

rat and that the additional iodine must have been absorbed through the skin and lungs (presumably from ordinary air), but the values which von Fellenberg has given for the iodine content of air would make the increases noted impossible during the time of the experiment; i. e. the rate increased from 4,718-4,767 to 8,774-8,894 micrograms in four days. Wheat grains were raised in one hour of ultraviolet irradiation from 7 to 16 micrograms, and the author says this is in harmony with von Fellenberg's observation that the flora has more iodine in the summer! On page 145 are given data on five cretins in whom thyroids had been implanted. To use this procedure seems a pity, since it is well known that thyroid administered by mouth or subcutaneously can be very much better controlled than thyroid grafts, which will not grow.

Symptoms and Signs in Clinical Medicine: An Introduction to Medical Diagnosis. By E. Noble Chamberlain, M.D., M.Sc., F.R.C.P., Physician to Out-Patients, Royal Liverpool United Hospital, Royal Infirmary Branch, Liverpool. With a chapter on The Examination of Sick Children. By Norman B. Capon, M.D., F.R.C.P., Lecturer in Diseases of Children, University of Liverpool, Liverpool. Second edition. Cloth. Price, \$8. Pp. 435, with 318 illustrations. Baltimore: William Wood & Company, 1938.

This edition is essentially the same as the first, and it must be remembered that physical diagnosis is a static rather than a dynamic science. There is, however, a change which adds to the satisfactory arrangement of the book, namely the collection into two chapters of all the laboratory data which had been scattered throughout the volume. There has also been added a table of biochemical standards. The book consists of thirteen chapters. The first two are more or less general and include the history taking, the physical examination and the external characteristics of disease. The next seven are devoted to important body systems, with two chapters on the nervous system. Succeeding these is a chapter on fever, another on examination of sick children and the two on laboratory data. As far as physical diagnosis is concerned, the chief objection to the book is the slight space devoted to important procedures in physical examination. Thus, percussion of the lungs is dealt with in what is equivalent to about two pages when four illustrations are deleted; incidentally, two of these, figures 77 and 78, are excellent, whereas figures 79 and 80 seem to be redundant. About the same amount of space is devoted to percussion of the heart. Auscultation is likewise dealt with rather briefly, as are other methods of physical examination which require the use of the four senses. To one of the senses is allowed a considerable amount of space; not only are a good many words written about the division of physical diagnosis which has to do with inspection, but also there are innumerable and excellent illustrations to explain the written contents. In addition to many photographs there are several colored plates and a few diagrams. The book can be recommended for the beginner in medicine. It is reasonably complete and deals largely with elementary essentials in the diagnosis of disease.

Über die integrative Natur der normalen Harnbildung. Von Gösta Ekehorn, D. R. med. Telle I, II und III. Paper. Pp. 616; 619-1137; 1139-1431. Helsingfors: Mercators Tryckeri, 1938.

This wordy treatise is written by a native of Sweden in German and published in Finland; the first sentence of the preface states that it is a continuation of the author's previous book "Principles of Renal Function," which was published in English. The author first assumes that the glomerular filtrate is an ultrafiltrate of the blood and that the kidney tubules are impermeable to creatinine and only slightly permeable to urea. He calls them "schlackenstoff" to distinguish them from "schwellenstoffe," or threshold substances, including salts and water. Later, however, he spends much space disproving the impermeability of the tubule for creatinine. He states that the glomerular capillary blood pressure may be so high as to equal half the normal systolic arterial pressure, and therefore the glomerular filtrate volume averages about one fourth the renal blood volume. On the assumption of impermeability to creatinine, he quotes tables from Rehberg's 1926 publication to show the amount of ultrafiltrate and the amount of absorption of salt, water and urea back into the blood. The author states that when the reabsorption of water decreases during diuresis the reabsorption of urea decreases and that therefore there is more water and urea in the urine. The glomerular filtrate, he says,

is about 125 times the volume of the urine. Therefore 124 volumes are reabsorbed. He accepts the opinion that the increase in the nonfiltrable constituent of the blood as it passes through the glomeruli controls the amount of reabsorption of salt in the convoluted tubules of the first order. The book might be said to end with the pointing out of many unsolved problems in kidney physiology and of analogies between these problems and problems connected with the secretion of gastric juice.

Nursing Mental Diseases. By Harriet Bailey, R.N. Fourth edition. Fabrikold. Price, \$2.50. Pp. 264. New York: Macmillan Company, 1932.

This is a concise, practical, informative and interesting textbook for the instruction of nurses in the understanding and management of psychiatric patients. The early chapters deal with the history of the care of the mentally sick and with legal aspects of mental disorders, followed by a general discussion of personality development, causes and classification of mental disorders, symptoms and special nursing measures required in the care of psychotic patients. Especially commendable is the chapter detailing such nursing procedures as the administration of food, relief of insomnia, prevention and treatment of bed sores, attention to evacuation of the bowels and bladder, the management of excited patients and precautions against suicide, which are so important and sometimes so difficult in the care of the mentally ill. Chapters VIII to XXI describe specific mental disorders and, in brief, the special nursing procedures requisite to each. Later chapters deal with methods of treatment such as occupational, recreational and physical therapy, which in hospitals are usually under the supervision of specially trained workers but which the nurse may be called on, especially in private practice, to direct. In conclusion there is a valuable discussion of measures for the prevention of mental illness and the promotion of mental health, and finally an excellent bibliography of suggested supplementary reading, including not only didactic but also popular writings on the subject of mental illness such, for example, as Shakespeare's *King Lear* and *Timon of Athens*.

Ker's Manual of Fevers. Revised by Frank L. Ker, B.A., M.B., Ch.B., Senior Assistant and Deputy Medical Superintendent, Little Brownhill Hospital, Birmingham, England. Fourth edition. Cloth. Price, \$1.50. Pp. 354, with 15 illustrations. New York & London: Oxford University Press, 1939.

In the preface of this edition the son of the original author has expressed his desire to adhere to the aims of his father. As a consequence revisions in the text consist chiefly of slight changes or additions made necessary because of advanced knowledge, particularly with respect to treatment, including chemotherapy. To any one familiar with the subjects discussed, the contents of the book should be refreshing. It is readily apparent that the clear and complete descriptions of the various contagious diseases as presented by Claude B. Ker are the result of keen observation, careful thought and extensive experience. There are few technicalities but much information that is sound and practical. The volume is likely to receive its greatest appreciation from those who have had training in contagious disease hospitals. To the medical student the chapters on smallpox and typhoid should be of special interest. The six plates, though not in color, are all good, particularly the ones illustrative of smallpox. A table of infectious diseases at the close of the volume will be valued by the student.

Bericht über den VIII. Internationalen Kongress für Unfallmedizin und Berufskrankheiten Frankfurt a. M. 26. bis 30. September 1938. Unter der Schirmherrschaft des Herrn Reichsarbeitsministers Franz Seldt. Bänden I und II. Paper. Price, 50 marks per set. Pp. 322; 323-1577, with 145 illustrations. Leipzig: Georg Thieme, 1939.

This report contains the proceedings and papers of the eighth International Congress for Industrial Medicine and Occupational Diseases, held in Frankfurt on the Main in 1938. The large number of papers presented by European workers affords the American reader an excellent opportunity to gain insight into their practices and experiences. Although most of the papers are in German, French or Italian, many of the longer ones are provided with excellent English summaries. Volume I contains a joint discussion, by the two sections of the congress, of pre-disposition and wear and tear in their relation to industrial

accidents and occupational diseases. Such subjects as the relation of the condition of the body to the effect of injuries, cutaneous conditions as a factor in occupational injuries and neurologic and genetic aspects indicate the extent to which this topic is discussed. In one paper special attention is given to the problem in the so-called mass production industries. Volume II, the larger of the volumes, contains the papers of the section on industrial surgery and those of the section on occupational diseases. The industrial surgeons confined their discussions to two topics: (1) injury to the peripheral nerves with the exception of the sympathetic system and (2) injuries to the foot. The cause, nature and modes of treatment of these injuries are discussed thoroughly and at length by many world authorities. The section on occupational diseases provides papers on scores of topics, including hydrocarbon solvents, manganese pneumonia, occupational cancer, silicosis, asbestosis, carbon bisulfide and chlorinated hydrocarbons, chiefly trichlorethylene. It appears from the proceedings of this international body that the problems relative to occupational diseases are at this time essentially the same for all the industrial countries of the world.

Gynaecology. By Herbert H. Schlink, Lecturer and Examiner in Gynaecology, University of Sydney, Sydney. Cloth. Price, 32s. 6d. Pp. 557, with 181 illustrations. Sydney & London: Angus & Robertson, Limited, 1939.

This was designed as a textbook for students at the University of Sydney and as such is an admirably prepared volume. Particularly well done are the chapters on anatomy and physiology and the chapters dealing with prolapse and displacement of the female generative organs. The chapters on history taking and methods of examination are at the end of the book, subjects which it appears should be taken up at the outset in a study of any specialty. The chapters on operative gynecology, postoperative complications and treatment and the descriptions and designations accompanying the illustrations are incomplete and even confusing at times, while the author is much too dogmatic in expressions relative to the choice of operation, particularly with regard to the treatment of retroversion by round ligament shortening. This may, as stated previously, be an excellent textbook for use by Schlink's students at Sydney. In view of the already published and most excellent textbooks of gynecology available, this book adds nothing of value for the American practitioner or student.

Problems in Prison Psychiatry. By J. G. Wilson, M.D., Director, Division of Hospitals and Mental Hygiene, Department of Welfare of the State of Kentucky, and M. J. Pescor, M.D., Clinical Director, United States Public Health Service Hospital, Fort Worth, Texas. Cloth. Price, \$3. Pp. 275. Caldwell, Idaho: Caxton Printers, Ltd., 1939.

This is an extremely interesting pioneer work directed toward understanding the mental problems of criminals. The authors have worked with many prisoners and attempt an understanding of the cause, therapy and prevention of neurotic and psychiatric crimes. The work should be studied by prison administrators as well as physicians having to do with prisons. It is a sound psychiatric study and is the best of its kind so far attempted.

Radiologie clinique du cœur et des gros vaisseaux. Par Ch. Laubry, P. Cottenot, D. Routier et R. Helm de Balsa. Fascicules I et II. Cloth. Price, 430 francs. Pp. 163; 164-340, with 1,049 illustrations. Paris: Masson & Cie, 1939.

There are three parts to the monograph. The first is concerned with the utility of x-ray examination of the cardiovascular system and the various technics by which this method may be applied to such examination. The second part is concerned with the appearance of the normal heart in all its variations and the factors at work in the production of such normal differences. The third part is concerned with organic heart disease and considers rheumatic, congenital, syphilitic, chronic myocarditic, hypertensive and pulmonary heart disease in the order named. Then the pericardial involvements and the picture produced by heart failure follows. The appearance produced by extracardiac mediastinal masses is finally considered. The bibliography is extensive. This two volume work on cardiovascular roentgenology is highly recommended. It is beautifully and completely illustrated and the terse discussion is quite adequate. The x-ray delineation of the right and left sides of the heart separately in the cadaver by means of barium sulfate injections is illuminating.

Regeneration: ihre Anwendung in der Chirurgie. Mit Einem Anhang: Operationslehre. Von Dr. Johann v. Ertl. Paper. Price, 24 marks. Pp. 246, with 388 illustrations. Leipzig: Johann Ambrosius Barth, 1939.

This book reports the principles used and the results obtained in the care of about 60,000 patients with war injuries. It is purposely written twenty years later in order to give the late results. It is a general treatise on the theory behind the work done rather than a statistical survey. The late results are shown by numerous reproductions of photographs and x-ray plates. There is a short incomplete historical sketch, followed by a general discussion of the regeneration and transplantation of the various tissues, but little of which is the author's original work. The principle of repair of tissue defects in layers is stressed repeatedly, as are the biologic conditions of successful transplantation of tissues in general. These are well accepted concepts. The author makes frequent use of thin flexible bone grafts, so-called osteogenic grafts, and reports excellent results. A small number of small bone chips are removed attached to the periosteum in preparing this type of graft. It is used as an onlay graft or doubled back on itself in replacing bone defects, as in the lower jaw. The book could be more detailed in describing technical procedures. The illustrations and sketches cannot be compared as to quality with those of older German writings.

The Mechanism of Thought, imagery and Hallucination. By Joshua Rosett, Professor of Neurology in Columbia University, New York. Cloth. Price, \$3. Pp. 289, with 12 illustrations. New York, Morningside Heights: Columbia University Press, 1939.

A tremendous amount of effort has been put into this great tome in an effort to explain the mechanisms of mental processes on a strictly organic basis. Biologic data and the experiments with diseases affecting man are utilized in deducing the mechanisms of thought. Each chapter outlines a phase of the subject and is followed by a detailed summary and bibliography. Thought, imagery and hallucination are discussed and described, but the explanations are not satisfactory even though based on physiology. We still appreciate Sherrington's statement that understanding the physiology of the brain leads us but little closer to understanding mental processes.

Troubles du myocarde dans les anémies: Etude clinique, expérimentale et pathogénique de l'insuffisance nutritive d'origine sanguine. Par le Docteur Charles Bauge. Paper. Pp. 124, with 9 illustrations. Paris: Librairie E. Le François, 1939.

This monograph, based on analysis of six case reports and seventeen animal experiments correlated with a thorough review of the literature, deals with the effect of acute hemorrhagic anemia and chronic progressive anemia on the heart. The author properly points out that the effect of anemia on the heart constitutes an important part of the clinical picture. As a result of his analyses the author states that gallop rhythm, an increase in the magnitude of the heart activity fluoroscopically, the presence of heart murmurs and low voltage and low T waves constitute the elements in chronic anemia. Occasionally, coronary electrocardiographic changes are present. This is more prevalent in the acute form. The circulatory changes are due as much to the changes in circulatory blood volume and composition of the plasma in the acute form as to the loss of hemoglobin. Transfusion is considered the most important method of treatment. The monograph will repay the cardiologist for perusing it. Perhaps the assembly of data dealing with this subject will inspire further investigation of this all important subject.

How to Psychoanalyze the Bible. By H. F. Haas. Cloth. Price, \$1. Pp. 116. Orangeburg, S. C.: Haas Publication Committee, Publishers, 1939.

The author of this book, apparently a layman who bears the same name as the publishers, attempts to expound a rationalistic attitude toward Christianity and the Bible. He exhorts the reader to adopt the methods of reason and science and to free himself from the influence of the superstitions and fears which have been distorting the true meaning and value of Christ's teaching. Much use is made of such terms as "psychoanalysis," "unconscious" and "repression," but in such a way as to make obvious that the author has no knowledge of their true meaning. The book can in no way be recommended as a serious psychological study of the Bible.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Appendicitis Allegedly Resulting from Trauma.—Keahey fell in the course of his employment, Dec. 5, 1932, injuring his back and hip, and was paid compensation under the Texas workmen's compensation act. On March 21, 1933, he underwent an appendectomy. July 3, 1935, more than two years later, he underwent an operation for the relief of intestinal strangulation caused by adhesions which had developed following the appendectomy. He died the following day. His widow and children claimed compensation under the Texas compensation act, attributing death to the original industrial accident, but the industrial accident board rejected their claim. They then instituted proceedings before the district court, Wheeler County, Texas, which rendered judgment on a verdict of the jury in their favor, and the employer's insurer appealed to the court of civil appeals, Texas, Amarillo.

The workmen's compensation act, said the court of appeals, provides compensation for injuries arising out of and in the course of employment. The term "injury" is limited by the act to mean "damage or harm to the physical structure of the body and such diseases or infection as naturally result therefrom." It follows, then, that injury or death resulting from intervening, independent agencies is not compensable. Thus, if by reason of an industrial injury a workman's resistance against diseases and infections coming from other sources is reduced and he contracts and dies from those diseases and infections, his death is not compensable. *Texas Employers' Ins. Ass'n v. Burnett*, 105 S. W. (2d) 200.

To prove that the intestinal adhesions and the surgical operation performed on the workman July 3, 1935, to remove them were the ultimate result of the industrial injury of Dec. 5, 1932, the claimants called Dr. York, who had treated the workman in March 1935 shortly before the last operation but had not seen the workman prior to that time. Dr. York first testified that he thought the injury contributed to the disease condition of the appendix. Later he stated that in his opinion the injury caused the appendicitis but said he "couldn't just qualify on that." Still later he testified that in his belief the injury caused the appendicitis. On cross-examination he stated that he could not say "just exactly that the injury was the sole cause, but it was a highly contributing cause," because he believed that inflammation resulted from the industrial accident and, by a process of contiguity, progressed through the muscles, organs and tissues of the body from the locus of the injuries through the psoas and other muscles in the lumbar region and through the peritoneum and finally reached and involved the appendix, necessitating the appendectomy on March 21, 1933.

The value of Dr. York's testimony, said the court, depends on whether or not there was present in the region of the appendix or in the appendix itself, when the appendectomy was performed in March 1933, inflammation or infection which had originated at the locus of the injuries to the workman's back three and a half months prior thereto and whether or not such inflammation or infection caused the appendicitis. The testimony of the physician who had performed the appendectomy in question and the nurse who had assisted him was quite clear that at the time that the appendectomy was performed there was no inflammation of the tissues surrounding the appendix or bowels or any part of the abdominal cavity except the appendix itself, nor was there any black, blue or bruised spot on the patient's back or elsewhere on the body and that the workman "was suffering from an ordinary case of appendicitis." That physician further stated that the conditions which, in the opinion of Dr. York, existed in the region of the appendix and brought about its disease condition and necessitated the appendectomy did not exist. This physician further testified that he had never known or heard of a case of appendicitis resulting from a bruised back or hip and that he had never read any medical authority which reported such a case. He stated that,

if the appendix had been affected by inflammation proceeding from the injuries in the patient's back, the organs and tissues in the region of the appendix and between the appendix and the locus of the injuries would have shown an inflamed or infected condition, but that he found no evidence of any inflammation or infection of any organs or tissues except the appendix. He stated that if such inflammation or infection could be so communicated it would have to go through the heavy lumbar muscles which form the back side of the body wall and then through the psoas muscle, both of which are very thick, and then it would have to proceed through the bony pelvis or ilium and the back bone and then the kidneys and other tissues in that region, and that inflammation from a bruise could not proceed through such tissues, muscles and portions of the body so as to cause appendicitis. If such a thing were possible, he said, the injury would have to be so tremendous that the patient would be dead before the results could be transmitted through such heavy structures as intervene between the back and the appendix. In his opinion there could be no possible connection between a back injury and the development of appendicitis, especially after so long an interval.

In the opinion of the court, Dr. York's testimony merely raised a surmise or suspicion that the attack of appendicitis may have been the result of the injuries to which the workman was subjected three and one-half months prior to the attack of appendicitis and did not warrant the trial court submitting the case to the jury. If, said the court, there was any connection between the original injury and the appendicitis, there must have been present, in the region of the appendix at the time that operation was performed, inflammation or infection that had its origin in the injury to the workman's back, and the existence of this condition is the very basis of Dr. York's opinion. The testimony of the operating physician and his nurse, however, leaves no room for doubt that the appendical region at the time the appendectomy was performed was, as a matter of fact, free from any such infection or inflammation and thus destroys the theory and opinion of Dr. York. The trial court should have instructed a verdict in favor of the insurance company.

The court of civil appeals accordingly reversed the judgment in favor of the widow and the children.—*Traders & General Ins. Co. v. Keahey (Texas)*, 119 S. W. (2d) 618.

Malpractice: Trench Mouth Diagnosed as Syphilis.

The plaintiff consulted the physician defendant, July 28, 1936, relative to sore mouth, throat and gums, informing him that she had had "trench mouth" about two years before. The physician, without resorting to a Wassermann test, which he told her was unnecessary, from a superficial examination of the mouth and gums made a diagnosis of syphilis in an advanced stage and instituted a course of bismuth and arsenic treatments. In about two weeks her eyes became inflamed and watery, and in about three weeks her feet, ankles, arms and legs began to swell. The treatments, however, were continued until September 13. She was hospitalized September 17, at which time she was semiconscious and had pimples all over her skin from which pus and water exuded. She remained in the hospital under the defendant's care for thirteen days with no apparent improvement and was then removed to another hospital and placed under the care of Dr. Turner, who made a diagnosis of exfoliative dermatitis (arsenical), Vincent's angina and pyalism or salivation. Eventually her hair fell out, she shed her finger and toe nails and she was affected with "lockjaw" to the extent that she could open her mouth but slightly and was unable to masticate her food. She brought suit against the defendant physician, who defended by contending that her injuries, if any, were due to an idiosyncrasy.

At the trial medical experts testified that it was not the accepted, standard or proper practice for a physician to attempt a diagnosis of syphilis without a Wassermann test, a microscopic test or a blood smear. With respect to the propriety of the defendant's continuing to administer arsenic and bismuth in the presence of inflammation of the patient's eyes, the swelling of her limbs and her entire body and the dermatitis, there was medical evidence that when symptoms of arsenic poisoning are present in a patient undergoing the therapy in question, the proper course is immediately to discontinue the treatment and

give the patient something to counteract the ill effects of the treatment. There was further medical testimony that subsequent to the defendant-physician's release from the case other physicians had made Wassermann blood tests of the patient, that none of these physicians had made a diagnosis of syphilis and that none of these physicians had treated her with arsenic or bismuth. At the close of the plaintiff's case, the trial court directed a verdict in favor of the physician-defendant and the patient appealed to the court of civil appeals of Texas, Amarillo.

The sole question to be determined by the appellate court concerned the right of the trial court under the testimony to direct a verdict in favor of the physician. While a physician, said the court of civil appeals, does not insure results, he is required to have such reasonable skill as the profession generally possesses and to exercise such skill with reasonable care and diligence. The physician here offered no testimony and the evidence adduced by the patient is undisputed that the physician informed the patient that he could make or have made a Wassermann test, that such a test or a microscopic blood test was in common use in the locality in which the defendant practiced and generally by the profession and was deemed by them essential in order to diagnose the disease of syphilis; and that the defendant made no such test but relied on the superficial examination of looking into and swabbing the mouth and throat, which was undependable and not relied on by the medical profession to determine the existence of such disease. The evidence raises fact issues as to a negligent diagnosis and as to whether the patient's damage resulted from the treatments of arsenic and bismuth administered by the defendant. The jury should have been permitted to determine these issues. The judgment in favor of the defendant-physician was accordingly reversed and the cause was remanded.—*Gifford v. Howell* (Texas), 119 S. W. 578.

Taxes: Antivivisection Activities as Charitable Activities.—For federal estate tax purposes, the Commissioner of Internal Revenue refused to allow as a deduction from the gross estate of a testator a legacy left to the New England Antivivisection Society, and the executor of the will sought a reversal of the commissioner's ruling in the United States district court, D. Massachusetts.

The federal estate tax law under which this case arose provided that for the purpose of taxation the value of the net estate shall be determined by deducting from the value of the gross estate:

The amount of all bequests, legacies, devises, or transfers . . . to or for the use of any corporation organized and operated exclusively for religious, charitable, scientific, literary, or educational purposes, including . . . the prevention of cruelty to children or animals, no part of the net earnings of which inures to the benefit of any private stockholder or individual . . .

The executor contended that the New England Anti-Vivisection Society is an organization organized and operated exclusively for charitable purposes within the meaning of the federal estate tax law.

The commonly understood and narrow meaning of the word "charity," the court said, is good will to the poor and suffering, almsgiving and provision for the care or relief of the poor (Webster's International Dictionary, ed. 2). In the law, however, a far broader and more comprehensive significance has been given to the word. The most generally accepted definition of it is found in the extensively cited case of *Ould v. Washington Hospital for Foundlings*, 95 U. S. 303, 24 L. Ed. 450, wherein it was said that "a charitable use, where neither law nor public policy forbids, may be applied to almost anything that tends to promote the well-doing and well-being of social man." It was clear to the court in the present case that what is done out of good will and a desire to add to the improvement of the moral, mental and physical welfare of the public generally comes within this meaning of the word "charity." The charter of the society provides that it was organized for the purpose of systematic, scientific research relative to the practice of vivisection—its relation to science and its effect on those who practice it and on society; exposing and opposing secret or painful experiments on living animals, lunatics, paupers or criminals; urging education and legislation in pursuance of these ends, and issuing posters, pamphlets and other publications. In the opinion

of the court, the aims and purposes of the organization were for the public good and were charitable within the meaning of the federal estate tax law.

The evidence disclosed that the society had sponsored several bills in the Massachusetts legislature asking that dogs be exempt from the practice of vivisection. The circumstances of the society favoring the passage of this legislation, the court said, did not in any way place the society outside the provisions of the federal estate tax law. This legislation was merely incidental to carrying out the purposes and accomplishing the purposes of the society. The help of the legislature was necessary to enable it to advance its aims. Such activity was, as expressed in the case of *Slee v. Commissioner of Internal Revenue*, 42 F. (2d) 184, 72 A. L. R. 400, "mediate to the primary purpose, . . . ancillary to the end in chief." This incidental activity, the court concluded, did not militate against the contention that the society was "exclusively" organized and operated for charitable purposes. The ruling of the Commissioner of Internal Revenue was therefore reversed.—*Old Colony Trust Co. v. Welch*, 25 F. Supp. 45.

Workmen's Compensation Acts: Refusal of Employee to Accept Medical Treatment Tendered by Employer.—

The workmen's compensation act of Indiana provides that during the first ninety days after an injury the employer "shall furnish or cause to be furnished, free of charge to the injured employee, an attending physician, for the treatment of his injuries, and in addition thereto such surgical, hospital and nurse's services and supplies as the attending physician or the industrial board deem necessary." The refusal of the employee to accept such services and supplies, when so provided by the employer, bars the employee from all compensation during the period of such refusal.

On Oct. 22, 1937, the claimant, Pipkin, as the result of his employment with the defendant corporation, sustained a right inguinal hernia. He consulted two "company doctors," furnished by the defendant, who advised against an operation because he did not have a "complete hernia." He also consulted two other physicians of his own choice who diagnosed his condition as a "complete hernia" and advised that he undergo an operation for its repair. On November 19 he requested the defendant to provide such an operation. This request was at first refused but later the defendant agreed to provide the services of one of its "company doctors" for such an operation. The claimant, however, refused to accept such services because he believed that the company doctor "did not know what was the matter with him." Instead, he submitted to an operation by a physician of his own choice. Later, he filed a claim with the industrial board of Indiana for compensation under the workmen's compensation act. The board, however, found that by his refusal to accept the medical services tendered by his employer he had forfeited his right to compensation. From an award of the board denying compensation, the claimant appealed to the appellate court of Indiana, in Banc.

The workmen's compensation act, said the appellate court, bars any employee from compensation who refuses to accept such surgical, hospital and nurse's services as the attending physician, who is furnished by the employer, or the industrial board may deem necessary. As was held in *Witte v. J. Winkler & Sons, Inc.*, 98 Ind. App. 466, 190 N. E. 72, the employee's refusal to accept such services does not bar his claim for compensation unless his refusal is unreasonable. Whether a refusal is or is not reasonable will depend on the facts of each particular case and is a question for the determination of the industrial board in its sound discretion. In the judgment of the court, the evidence did not show conclusively that the claimant's refusal to accept the company surgeon's services was reasonable. The qualification of the company surgeon and his ability to perform the operation were proved and undisputed. Lack of confidence in the physician, which was the claimant's sole reason for refusing to accept his services, was not a sufficient reason. If it were held to be so, it would in effect be holding that the employer must furnish a surgeon satisfactory to the employee, whereas the workmen's compensation act does not give the employee the privilege of choosing his own physician. Accordingly, the appellate court affirmed the award of the industrial board denying compensation.

Judge Laymon, in a special dissenting opinion, disagreed with the opinion of the majority of the court. In his opinion, the mere fact that an employee desires to submit to the services of a physician of his own choosing, and, by reason of that fact alone, all other facts being equal, refuses the same services proffered by his employer, does not of itself make such a refusal unreasonable. It would indeed be a harsh rule that bound an employee to submit to a surgical operation, where life and death are at stake, and to accept the services of a physician who advised against the operation, after diagnosing the case and consulting the patient, simply because the physician is being furnished by the employer. The dissenting justice relied for his opinion on the case of *Witte v. J. Winkler & Sons, Inc.*, supra, in which the court said:

The question of whether an employee is justified in refusing to submit to a surgical operation proffered by his employer is one that has to do largely with the personal element. It is the employee upon whom the operation has to be performed, and his rights and interests should be seriously considered.

—*Pipkin v. Continental Steel Corporation (Ind.)*, 16 N. E. (2d) 984.

Foods: Liability of Packer and Retailer for Trichinosis.—One of the defendants, a packer of meats, sold smoked pork infested with parasites known as trichinae to another defendant, a retailer of meats. The defendant retailer ground or chopped up the pork and without cooking it made it into a sausage, which he smoked for about a week. The plaintiff purchased some of the sausage from the defendant retailer and subsequent to eating it developed trichinosis. He attributed the disease to the sausage and brought suit against both the packer and the retailer in the court of common pleas, alleging that the smoked pork and the sausage were unwholesome, adulterated, diseased and infected. From a judgment of the court of appeals, Lucas County, affirming the judgment of the court of common pleas in favor of the plaintiff, the defendants appealed to the Supreme Court of Ohio.

The defendants contended, among other things, that the plaintiff was negligent in eating the sausage without cooking it. They pointed out that there was no practical method of inspecting pork for the presence of trichinae and that if the laws of Ohio impose an absolute liability on them for the sale of pork infested with trichinae such laws violate the constitutions of the United States and of Ohio. But, said the Supreme Court, a manufacturer or packer of food warrants to the public generally that the food produced by it is fit for human consumption and it is liable for a breach of that warranty. In the instant case, the liability of the packer was primary and that of the retailer was secondary. Their liability was separate, not joint, and the packer and retailer should not have been sued jointly. Because of the misjoinder of the parties defendant, the Ohio Supreme Court reversed the judgment in favor of the plaintiff and remanded the cause for action in accordance with the court's mandate.—*Kniess v. Armour & Co. (Ohio)*, 17 N. E. (2d) 734.

Workmen's Compensation Acts: Hemorrhoids in Relation to Strain.—The claimant, Nantron, in the course of his employment with the defendant company, slipped while moving a "terrazzo machine" down a board onto a driveway. He claimed that he strained himself in trying to keep the machine from falling. From five to ten minutes later he felt pain in the region of the rectum. His condition was diagnosed as internal and external hemorrhoids with a rectal abscess at the base of one of the external ones. He was advised by a Dr. Webb to undergo an operation to eradicate his hemorrhoids. He disregarded this advice, however, and instead obtained treatment from another physician, who advertised the cure of piles "without a knife." An ischiorectal abscess developed which eventually resulted in the formation of a fistula. Because of his condition, he lost about three and one-half weeks of work, and after resuming work he apparently was no longer able to do heavy work. He filed a claim with the workmen's compensation commission of Missouri for compensation under the workmen's compensation act of Missouri, claiming that his hemorrhoids and subsequent complications had been caused by strain in the course of his employment. The commission found that his condition had not been caused by the accident and denied

compensation. From a judgment of the circuit court affirming that award, the claimant appealed to the St. Louis court of appeals, Missouri.

Dr. Webb, one of the physicians who treated the claimant and the only witness other than the claimant to testify, in answer to a hypothetical question incorporating all the essential facts of the case and asking whether the accident had anything to do with the production of the hemorrhoids, testified: "I cannot see how a mere slipping of any kind would produce hemorrhoids unless it would cause the whole rectum to turn out and he would have immediate pain with the thing; he would suffer immediately without a lapse of any time." In his opinion, if the hemorrhoids had been due to the accident there would not have been a lapse of from five to ten minutes between the injury and the pain. In the judgment of the court of appeals, Dr. Webb's testimony furnished competent and substantial evidence to support the award of the workmen's compensation commission denying compensation. Accordingly, the judgment of the circuit court upholding the commission's award was affirmed.—*Nantron v. General Tile & Marble Co. (Mo.)*, 121 S. W. (2d) 246.

Health Insurance: "Medical or Surgical Attention" Defined.—In an action on a policy of accident and health insurance the court of appeals of Georgia, division 2, agreed with the decision in *Federal Life Ins. Co. v. Summerhill*, 45 Ga. App. 829, 166 S. E. 54, that the term "medical or surgical attention" as used in an application for health insurance means "medical or surgical attention for some illness or disease of substantial importance or of a serious nature and not consultation, treatment, or attendance concerning some trivial or temporary indisposition or feeling which has passed away without affecting the general health." In the judgment of the court, the policy of insurance was not rendered void by the denial of the insured, who later became ill with tuberculosis, in her application for insurance that she had received "medical or surgical attention" during the two years preceding her application, when in fact during that period of time she had consulted three physicians because of her spitting of blood but had been informed by them that they could find nothing the matter with her.—*North American Acc. Ins. Co. v. Gilbert (Ga.)*, 199 S. E. 768.

Society Proceedings

COMING MEETINGS

- American Academy of Pediatrics, Cincinnati, November 16-18. Dr. Clifford G. Grulee, 636 Church Street, Evanston, Ill., Secretary.
- American Society of Anesthetists, Los Angeles, Dec. 14. Dr. Paul M. Wood, 745 Fifth Ave., New York, Secretary.
- American Society of Tropical Medicine, Memphis, Tenn., Nov. 21-24. Dr. E. Harold Hinman, Wilson Dam, Ala., Secretary.
- Association of American Medical Colleges, Cincinnati, Oct. 21-23. Dr. Fred C. Zapffe, 5 South Wabash Ave., Chicago, Secretary.
- Central Association of Obstetricians and Gynecologists, Kansas City, Mo., Nov. 2-4. Dr. W. F. Mengert, University Hospitals, Iowa City, Secretary.
- Central Society for Clinical Research, Chicago, Nov. 3-4. Dr. L. D. Thompson, 4932 Maryland Ave., St. Louis, Secretary.
- Gulf Coast Clinical Society, Mobile, Ala., Oct. 26-27. Dr. Clyde C. Rouse, 56 St. Joseph St., Mobile, Ala., Secretary.
- Inter-State Postgraduate Medical Association of North America, Chicago, Oct. 30-Nov. 3. Dr. W. B. Peck, 27 East Stephenson St., Freeport, Ill., Managing Director.
- National Society for the Prevention of Blindness, New York, Oct. 26-27. Mr. Lewis H. Carris, 50 West 50th St., New York, General Director.
- New York State Association of Public Health Laboratories, Albany, Nov. 3. Miss Mary B. Kirkbride, New Scotland Ave., Albany, Secretary.
- Omaha Mid-West Clinical Society, Omaha, Oct. 23-27. Dr. J. D. McCarthy, 107 S. 17th St., Omaha, Secretary.
- Pacific Coast Society of Obstetrics and Gynecology, Portland, Ore., Nov. 8-11. Dr. T. Floyd Bell, 400 29th St., Oakland, Calif., Secretary.
- Radiological Society of North America, Atlanta, Ga., Dec. 11-15. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse, N. Y., Secretary.
- Society for the Study of Asthma and Allied Conditions, Philadelphia, Dec. 9. Dr. W. C. Spain, 116 East 53d St., New York, Secretary.
- Southern Medical Association, Memphis, Tenn., Nov. 21-24. Mr. C. P. Loran, Empire Bldg., Birmingham, Ala., Secretary.
- Southern Surgical Association, Augusta, Ga., Dec. 5-7. Dr. E. Allen Ochsner, 1430 Tulane Ave., New Orleans, Secretary.
- Southwestern Medical Association, El Paso, Texas, Nov. 9-11. Dr. M. P. Spearman, 1001 First National Bank Bldg., El Paso, Texas, Secretary.
- Tri-States Medical Society of Texas, Louisiana and Arkansas, Marshall, Texas, Nov. 8-9. Dr. Robert K. Womack, Longview, Texas, Secretary.
- Western Surgical Association, Los Angeles, Dec. 15-16. Dr. Albert H. Montgomery, 122 South Michigan Blvd., Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

18: 133-260 (Aug.) 1939

Electrocardiographic Picture of Experimental Localized Pericarditis. H. B. Burchell, A. R. Barnes and F. C. Mann, Rochester, Minn.—p. 133.

*Prognosis of Intraventricular Block. L. G. Kaplan and L. N. Katz, Chicago.—p. 145.

*Effect of Oxygen on Exercise Tolerance of Patients with Angina Pectoris. J. E. F. Riseman and M. G. Brown, Boston.—p. 150.

Cardiac Neurosis Associated with Organic Heart Disease. S. Schnur, Brooklyn.—p. 153.

Acute Endocarditis in Wild Animals, with Especial Reference to Opossum. H. Fox, Philadelphia.—p. 166.

Effects of Whole Bile and Bile Salts on Perfused Heart. K. G. Wakim, H. E. Essex and F. C. Mann, Rochester, Minn.—p. 171.

Congenital Heart Disease: Report of Case of Dextroposition, Persistence of Early Stage of Embryonic Development of Heart, Persistent Truncus Arteriosus, Abnormal Systemic and Pulmonic Veins and Subdiaphragmatic Situs Inversus. D. W. Goldman and N. S. Stern, Memphis, Tenn.—p. 176.

Medionecrosis Aortae Idiopathica Cystica: Report of Case, with "Healed" Dissecting Aneurysm. J. T. Roberts, Cleveland.—p. 188.

Effects of Diphtheria Toxin on Heart. R. W. Boyle, C. H. McDonald and A. F. DeGroate, Little Rock, Ark.—p. 201.

Effect of Carbon Dioxide Inhalation on Peripheral Blood Flow in Normal and in Sympathectomized Patient. I. E. Steck and E. Gellhorn, Chicago.—p. 206.

Value of Special Radiologic Procedures in Detecting Cardiac Enlargement in Children with Rheumatic Heart Disease. Ann G. Kuttner and Gertrude Meyersbach, Irvington-on-Hudson, N. Y.—p. 213.

Measurement of Circulation Time with Calcium Gluconate in Patients Receiving Digitalis, with Electrocardiographic Studies. H. C. Wall, New Orleans.—p. 228.

Prognosis of Intraventricular Block.—Kaplan and Katz collected data from the hospital and clinical records of 126 patients whose electrocardiograms conformed to the criteria for the various varieties of intraventricular block, all showing a QRS duration of 0.11 second or more. They find that the character of the underlying disease, rather than the presence or absence of intraventricular block, determines the prognosis, although the presence of intraventricular block carries with it a high mortality rate in the first year (particularly in the first three months). The fatality rate within a year of the discovery of the conduction lesion was 80 per cent. Patients surviving this period have a materially better life expectancy, as another 10 per cent died within the second year and some of the remaining 10 per cent survived up to the seventh year. Apparently, a relatively benign type of intraventricular block occurs. Therefore the configuration of the electrocardiogram or the duration of the QRS deflection is of no prognostic significance.

Oxygen, Exercise Tolerance and Angina Pectoris.—Riseman and Brown describe the effect of breathing high concentrations of oxygen on the amount of work which seventeen patients with angina pectoris could do before pain developed. Breathing room air from the Douglas bags did not increase and in several instances actually caused a decrease in the amount of work which could be done before pain developed. Breathing oxygen from the Douglas bags enabled eleven of the seventeen patients to do considerably more work; four exercised until forced to stop because of fatigue without developing pain. Nine of these eleven patients were from 39 to 53 years of age. Two were 57 and 58 years old. Seven patients found that it required more than thirty-five trips (mount and descend a two step staircase) to induce pain while breathing room air; the other four patients felt pain on less than thirty-five trips. The remaining six of the seventeen patients were not able to do any more work while breathing oxygen. Only one of these patients was less than 53 years of age, and only two could perform more than thirty-five trips before angina developed. The data are consistent with the anoxemia theory of angina pectoris.

American Journal of Diseases of Children, Chicago

58: 457-690 (Sept.) 1939

*Obesity in Childhood: I. Physical Growth and Development of Obese Children. Hilde Bruch, New York.—p. 457.

Enterogenous Intramural Cysts of Intestines. D. J. Pachman, Chicago.—p. 485.

New Creatinine Standard for Basal Metabolism and Its Clinical Application. N. B. Talbot, Jane Worcester and Ann Stewart, Boston.—p. 506.

*Prevention of Diphtheria. H. P. G. Seckel, Chicago.—p. 512.

Old Tuberculin and Purified Protein Derivative in Tuberculin Patch Test: Comparative Study. H. Vollmer, New York, and Esther W. Goldberger, Staten Island, N. Y.—p. 527.

*Influence of Fluid and of Evaporated Milk on Mineral and Nitrogen Metabolism of Growing Children. Helen J. Souders, Helen A. Hunscher, Frances C. Hummel and Icie G. Macy, with assistance of Mary F. Bates, Marion L. Shepherd, Priscilla Bonner, J. Horton, A. Theresa Johnston and Louise Emerson, Detroit.—p. 529.

Hyperparathyroidism in Children: Report of Two Cases. W. E. Anspach and W. M. Clifton, Chicago.—p. 540.

Importance of Sensitization Mechanism in Clinical Phenomenon of Allergy: Possible Cause and Prevention. E. B. Shaw and H. E. Thelander, San Francisco.—p. 581.

Causes of Prematurity: I. Review of Literature. Nina A. Anderson and R. A. Lyon, Cincinnati.—p. 586.

Development of Obese Children.—Bruch studied the growth and development of 102 children from 2 to 13 years of age whose obesity was the principal clinical symptom and she compared her observations with results obtained in normal children. One aim of the study was to establish an objective basis for the diagnosis of the underlying endocrine disorder, if any, through an analysis of the progress in growth. She finds that in obese children growth in stature is in excess of the average normal but in harmony with the height development of children who mature early. Skeletal maturation is normal or advanced, certainly not delayed. The menarche in obese girls occurs early, in several instances before the age of 10 years. More than 50 per cent of the boys between 11 and 14 years old show signs of approaching or attained puberal development. The high weight of the obese child is considered as an exaggeration of a normal trend. The observations of intensive growth and early maturation are not consistent with theories which attempt to explain obesity on the basis of hypothyroidism and hypopituitarism; they agree with observations of the growth-promoting effect of abundant nutrition.

Prevention of Diphtheria.—Seckel discusses three factors relating to the prevention of diphtheria. 1. The best statistical method of checking the efficiency of active immunization against diphtheria is the so-called control series method. Diphtheria morbidity in immunized children is only one third to one eighth or even less than that of nonimmunized children. The statistical method of comparing the diphtheria morbidity in a given area before and after the introduction of immunization should not be used for scientific purposes except against the background of the secular waves of diphtheria morbidity. 2. In general, the "severity" of diphtheria in immunized children is less than in nonimmunized controls. If the clinical typology of diphtheria in immunized children is analyzed statistically (according to Escherich's types), there is found an overwhelming majority of cases of localized pharyngeal diphtheria, an almost complete disappearance of diphtheritic croup and about the same percentage of cases of toxic diphtheria as for nonimmunized children. The last two types of severe diphtheria are clinically less alarming in immunized children than they are in the control groups. 3. While antitoxin therapy reaches the natural limits of its preventive efficiency in cases of progressive toxic and malignant diphtheria, its limits may be in part overcome by nonspecific preventive treatment: parenteral protein therapy and intravenous dextrose therapy. The two types of nonspecific treatment are combined in a routine way with the injection of medium doses of diphtheria antitoxin and may, in cases of malignant diphtheria, be combined with each other.

Type of Milk and Mineral and Nitrogen Metabolism.—Souders and her collaborators determined the relative efficiency of plain fluid and of evaporated milk in meeting the mineral and nitrogen demands of the growing child. The nitrogen and acid-base mineral balance study was conducted on three healthy growing children (from 4½ to 6 years old) who received a basal diet of inexpensive foods, always available, which conformed with accepted nutritive standards. Each child received 400 Gm. of plain fluid milk daily for from twenty-five to forty days; during the following twenty to twenty-five days the same

quantity of plain evaporated milk (diluted 1:1) was included in the diet, and finally for the next twenty-five days each child received an identical quantity of irradiated evaporated milk (diluted 1:1). The only changes in the dietary during the three study periods was the substitution of milk. An added impetus in the forming of soft tissue resulted from the substitution of evaporated for fluid milk. This was shown by the parallel increases in retention of nitrogen, sulfur and potassium, which were not accompanied by corresponding increases in retention of the other elements. When irradiated evaporated milk was included in the diet, the increased calcium-phosphorus ratios of the retentions, the higher levels and more consistent trends of the acid-base balances and the increase in rate of gain in recumbent length all indicated a more rapid and stable rate of ossous formation.

Surgical Management of Patent Ductus Arteriosus.

Gross advises surgical obliteration for avoiding the complications to which the possessor of a patent ductus is liable. The operative steps for accomplishing this task were studied on post-mortem material, were practiced on dogs and are described. The author states that the ductus can be adequately exposed by an approach through the left pleural cavity, entering the superior mediastinum from its left lateral aspect. The feasibility of the method is demonstrated by the report of four patients on whom it was performed without mortality or complications. The results indicate that the ductus can be explored with safety and that it can be permanently ligated in most instances. It is important to recognize the condition, as surgery has much to offer these individuals. When there are no serious complicating cardiovascular lesions, surgical closure of the ductus can be performed with low risk and should ward off the dangers of subacute bacterial endocarditis and cardiac failure.

Massive Hemorrhage in Peptic Ulcer.—During a period of ten years, 135 cases of massive hemorrhage were encountered at the Bellevue Hospital, and twelve deaths occurred under conservative medical management. Hinton states that six of the patients died without blood transfusions and six after one or more transfusions. It would seem, therefore, that a definite percentage of massive hemorrhages will prove fatal under either

type of conservative management; i. e., regardless of transfusions. The location of the ulcer is an important factor in hemorrhage. It is the posterior duodenal ulcer (ten) that is most likely to prove fatal. Since the posterior duodenal ulcer frequently bleeds without having shown any previous gastric symptoms (18 per cent of the 135 patients had a negative gastric history), a posterior duodenal ulcer must be ruled out before one attributes the cause of gastric hemorrhage to gastritis. More than one negative gastrointestinal x-ray study should be obtained; the gastroscope is of no aid in making a diagnosis of posterior duodenal ulcer. Patients who continue to have hemorrhage under medical management become the province of the surgeon. In these cases operation during the acute stage may be a life saving measure. Blood transfusions may prove a helpful method of selecting the patients who urgently require such operation. When the blood pressure has fallen to 80/60, the erythrocyte count to 2,000,000 or less, and the hemoglobin to 35 per cent or thereabouts the patient needs supportive measures. A transfusion is the best way of overcoming the shock and the reduced blood volume. In addition, the transfusion may indicate whether operation is necessary or whether conservative measures should be continued. If, after 500 cc. of blood have been given, the red cell count, the hemoglobin and the blood pressure remain low, one may assume that a large vessel has been eroded. If the procedure is repeated and there is still no improvement, it is fairly conclusive evidence that further delay may prove fatal. A continuous transfusion of 1,000 cc. of citrated blood should then be started and the patient operated on as soon as possible. Further delay at this time would probably result in a fatality. The apparently hopeless case will withstand a subtotal resection surprisingly well.

Trachoma and Inclusion Blepharitis Viruses.—According to the studies of Braley on four baboons, the virus of trachoma, like the virus of inclusion blepharitis, produces a cervicitis which, when transferred to the conjunctiva, produces follicular conjunctivitis. Both viruses have an affinity for the epithelial hyperplasia. No conjunctival immunity is produced by infection in the cervix in either disease. The virus of inclusion blepharitis produces a short infection, while the virus of trachoma gives rise to a prolonged infection. The severity of symptoms produced by the two viruses is equal. Since the two viruses produce a similar pathologic condition, a similarity in their nature appears probable.

Concentration of Sulfanilamide in the Eye.—Mengel determined the concentration of sulfanilamide in the aqueous and vitreous after oral and local administration. He made the investigations on blind eyes. The amount of sulfanilamide absorbed into the aqueous from the conjunctival cul-de-sac was less than 0.1 mg. per hundred cubic centimeters, whereas a concentration of from 1.5 to 3.2 mg. per hundred cubic centimeters was found in the aqueous and vitreous after oral administration. Thirty-two minutes after its ingestion sulfanilamide was found in the vitreous in a concentration of 1.1

mg. per hundred cubic centimeters. The therapeutic value of sulfanilamide is known for infections caused by certain microorganisms elsewhere in the body, and therefore because of its rapid diffusion in the ocular fluids it should be considered equally valuable for the treatment of infections of the eye caused by these same organisms.

Healed Miliary Tubercles in Viscera.—Because of a tentative hypothesis that the small calcified bodies occurring in the liver, spleen and other parenchymatous viscera are miliary tubercles, Reichle and Work conducted a systematic study on material obtained at necropsy in 500 consecutive cases. In the search for these lesions, particular care was taken to examine the organs for manifestations of active, latent or healed tuberculosis. Approximately two thirds of the lungs were injected with solution of formaldehyde U. S. P. (diluted 1 to 10) and sectioned. The remaining material was examined in the fresh state. Partial necropsies and necropsies on stillborn infants, premature infants and infants who died before discharge from the hospital were excluded. There were forty-eight such cases; 452 cases remain. Nodules were found in one or several of the parenchymatous organs in ninety-one, an incidence of 20.1 per cent. This is a high incidence, since few conditions other than parenchymatous degeneration, hyperemia, edema, primary tuberculosis and arteriosclerosis occur in more than one fifth of the bodies coming to necropsy in the Cleveland City Hospital. The nodules were not phleboliths but true miliary tubercles. They are microscopically indistinguishable from small primary tubercles. Animal inoculation demonstrated the presence of tubercle bacilli. Their distribution points to hematogenous dissemination and their morphology to some association in point of time with the primary complex. The high correlation between apparent resistance to progressive tuberculosis and the incidence of these lesions leads to the suggestion that this dissemination acts as an autovaccination, conferring a relatively high resistance to reinfection. The spleen was most commonly affected, in seventy-three of the ninety-one cases, the liver in forty-seven and the kidneys in two. In the liver they were usually situated just beneath but not within the capsule and were only occasionally found in the deeper parenchyma. In the spleen they were commonly encountered deep in the pulp and infrequently beneath the capsule. The nodules bore no necessary relation to the structure of the organ in which they occurred or to its blood vessels. They could be easily extracted from the parenchyma but could never be shelled out of a casing such as is consistently found about a phlebolith. The number of lesions varied widely. In a few cases only one or two nodules were found while in others they numbered several hundred.

Methemoglobin, Sulfhemoglobin and Sulfanilamide.—Harris and Michel assayed quantitatively the effect of sulfanilamide on the formation of abnormal heme pigments. There were 960 blood examinations made on 476 patients. Methemoglobin, in quantities demonstrable by the hand spectroscope, was found in the erythrocytes of 277, or 58 per cent, of the patients at some time during the administration of sulfanilamide. The percentage of patients developing methemoglobinemia is roughly equal in the sexes but is higher in the young. Since the extent of methemoglobinemia did not increase markedly with the duration of dosage, it is not a cumulative effect of the drug and does not depend on the total dose of sulfanilamide. It is possible that the development of methemoglobinemia is favored by the presence of larger concentrations of circulating hemoglobin. To analyze this factor, 647 determinations on patients who showed methemoglobinemia at some time during their course of therapy were arranged in accordance with the hemoglobin content and the level of blood sulfanilamide. It was found that the percentage of bloods positive for methemoglobin in each sulfanilamide level group did not vary with the hemoglobin content. However, the average methemoglobin concentration showed a tendency to vary in direct relation to the amount of hemoglobin present, so that the average methemoglobin/total hemoglobin ratio remained rather constant at each blood sulfanilamide level. The blood hemoglobin levels were rather evenly distributed and unaltered by the age, sex and sulfanilamide concentration of patients. Sulfhemoglobinemia was more frequent after long courses of sulfanilamide but did not bear any relationship to age, sex or the concentration of sulfanilamide or

methemoglobin in the blood. On the basis of these observations, it is postulated that an active substance is normally produced in the course of sulfanilamide metabolism which causes the production of methemoglobin and sulfhemoglobin. The data presented are found to agree with the concept that methemoglobinemia depends on the balance of the formation of the active agent, oxidation of hemoglobin under the influence of the active agent and reduction of methemoglobin by the body.

Blood Volume in Nephritis.—Harris and Gibson observed the course of the plasma and total blood volume in nephritis. Three factors appear to be concerned in the regulation of the plasma volume: serum albumin concentration, nonprotein nitrogen concentration and the degree of anemia. Regardless of the stage of the disease, whether acute, subacute or chronic, with or without edema or renal insufficiency, the level of the plasma volume reflects the interrelationship of these three factors. The relationship of the changes in plasma and circulating erythrocyte volume is such that the total blood volume always remains below normal. With development of congestive heart failure, regardless of the degree of anemia present, an additional factor appears to be introduced resulting in an increased circulating erythrocyte volume and hence increased total blood volume. In the edematous stage hypoproteinemia tends to diminish, and, if present, anemia tends to augment the plasma volume. During diuresis there is a tendency for the plasma volume to increase chiefly in relation to the increase in the albumin fraction of the serum protein. Circulation time in the group of cases exhibiting subacute glomerular nephritis with edema (nephrosis syndrome) was slower than in the group with chronic nephritis without edema. The lowered metabolism characteristic of the former group may explain this paradoxical observation.

Dark Adaptation, Vitamin A Metabolism and Cirrhosis.—Whether vitamin A deficiency occurs in patients with hepatic disease whose intake of the vitamin is adequate and who are not jaundiced was determined by Patek and Haig by studies on vitamin A metabolism in twenty-four cases of cirrhosis of the liver. The studies show that patients with cirrhosis of the liver may be deficient in vitamin A. The deficiency is not attributable to an inadequate intake of the vitamin in their food. Although the selected cases were free of jaundice, it is possible that malabsorption contributed to the deficiency. The patients' resistance to oral therapy might be so interpreted. Abnormal dark adaptation was observed in nineteen of the twenty-four cases. In certain cases both elevation of the final rod and cone thresholds and delay of rod dark adaptation occurred. In most instances only the latter change took place. These changes were unrelated to jaundice. They tended to persist in the presence of a nutritious diet, rich in vitamin A. The oral and parenteral administration of vitamin A concentrates was followed by extensive improvement. Cone and rod thresholds were lowered and speed of adaptation was increased. This improvement was only partially maintained after treatment was discontinued. These data suggest that abnormal dark adaptation in patients with cirrhosis of the liver is due chiefly to altered intermediary metabolism of vitamin A.

Comparison of Tuberculin Tests.—Over a period of two months Peck and Wegman performed tuberculin tests on 880 school children. Their ages varied from 5 to 21. The first and second purified protein derivative doses were injected intradermally and the Vollmer patch test was applied to the skin. The first purified protein derivative dose was injected and the patch test applied on the same day and both were read two days later. Those children who were negative to the first purified protein derivative test were tested with the second purified protein derivative dose and this was read two days later. In all cases in which the patch test was positive, it was found that it was as definite on the second day as it was on the first day, or even stronger, indicating that one may read the test forty-eight hours after removal of the adhesive tape just as well as after twenty-four. At least one of the three tests used was positive in 319, or 36.2 per cent, of the children. The patch test was far inferior to purified protein derivative in detecting tuberculin reactors. It was not even as good as the first strength of purified protein derivative, even though the patch test did pick up some reactors who were negative to the first strength of purified protein derivative. The patch test did pick up eighteen, or 9.6 per cent, of the 188 in which the first dose of purified protein derivative was negative. By contrast, however, the first dose of purified protein derivative detected fifty-five, or 24.4 per cent, of the 225 in which the patch was negative. It seems to be clear that the patch alone cannot replace purified protein derivative either as a diagnosticum for the individual patient or as a case-finding procedure in public health work. Because of the obvious convenience of the patch test, a possible field of usefulness suggests itself. One might employ the patch for the primary test in place of purified protein derivative, recognizing that if the test is negative it must be followed by the second strength of purified protein derivative before a definite opinion can be given.

Chest Roentgenograms of Tuberculous Contacts.—Rosenberg and Levine studied 1,852 roentgenograms of the chests of 584 infants, varying in age from birth to 5 years, from tuberculous homes. Among 379 cases in which Mantoux tests were negative, the incidence of tracheobronchial shadows alone was 6.8 per cent and the incidence of parenchymal shadows was also 6.8 per cent. Among 205 cases in which Mantoux tests were positive, the incidence of tracheobronchial shadows was 9.2 per cent and that of parenchymal shadows was 40 per cent. Increased tracheobronchial shadows persisted for more than three months in 26.6 per cent of the cases in which the Mantoux tests were negative, as against 71.3 per cent of the Mantoux tests were positive. Parenchymal cases in which the tuberculin test was positive. Parenchymal shadows persisted on subsequent examination for three months or more in eight of sixteen of the negative Mantoux cases and in sixty-one of the sixty-six positive tuberculin cases. Infants dying of tuberculosis generally show demonstrable parenchymal shadows on a roentgenogram. Since miliary tuberculosis was the most frequent cause of death in the series of cases, the diagnosis of lethal forms of tuberculosis by x-ray examination

was readily made. Increased tracheobronchial shadows in infancy may not be accepted as pathognomonic of tuberculosis, even in the presence of a positive Mantoux test. However, a majority of the parenchymal lesions in tuberculin positive infants are probably tuberculous in nature.

Phenolphthalein Test in Gastrointestinal Disease.—In order to determine the rationale of the phenolphthalein test in the diagnosis of gastrointestinal disease, as suggested by Woldman, 203 patients were submitted to the test by Banks and Barron. Of these, fifty-two had intrinsic lesions of the gastrointestinal tract. The remaining 151 had a variety of conditions other than those of the gastrointestinal tract or no demonstrable pathologic lesion and served as controls. Only thirty-six positive tests were obtained in the group of fifty-two patients. Carcinoma of the stomach and intestine gave the highest proportion of positive results, whereas negative tests were found in two cases of esophageal carcinoma, possibly owing to the brief period of contact between the drug and the diseased area. Ulcers of the mouth and pharynx gave uniformly positive tests. Of twenty-two patients with gastric or duodenal ulcer, approximately one third yielded negative results. More detailed analysis of these failures revealed that gastric stasis or pyloric obstruction with fluid retention and possible precipitation of the drug might account for several, and one patient had an ulcer high in the cardia. No explanation was apparent in the remainder. There were three failures in four cases of chronic ulcerative colitis or amebic dysentery characterized by frequent liquid stools daily. Here again insufficient contact due to the hypermotility of the intestine may have been a factor. In the control subjects the test yielded 127 negative and twenty-four positive tests. The test was consistently negative in cases of hysteria, unexplained syncope, anorexia nervosa, diabetes and osseous disease. Positive tests were found especially in serious and advanced heart disease with pulmonary edema, paroxysmal nocturnal dyspnea, coronary occlusion, acute toxemia, infection and malignant metastasis. One must assume either that breaks in the mucous membrane of the alimentary canal frequently exist under such conditions or that the vitality of the cells is so impaired that the enteric membrane no longer acts as an efficient barrier to the drug. Several asthmatic patients also excreted significant amounts of free phenolphthalein in the urine. It is the authors' impression that the test may find its greatest field of usefulness among ambulatory patients, in whom the chance of obtaining false positive tests because of severe toxemia or far advanced systemic disease would be largely eliminated. In view of the rapid absorption from oral lesions which might obscure a more serious condition lower down, the patient should drink the test fluid through a straw, rinsing the mouth immediately and thoroughly with water without swallowing further. Excessive salivation should be noted and prevented from interfering with the test. In cases of suspected gastric disease, the test is best done after gastric lavage or gastric analysis in order to obviate retention and consequent excessive dilution of the test liquid. At times catheterization to obtain the urine specimens may be indicated, as in prostatic cases in watery diarrhea.

Oxygen for Abdominal Distention and Emphysema.—Congdon and Burgess used 95 to 98 per cent oxygen in the treatment of forty cases of abdominal distention and three cases of subcutaneous emphysema treated. Twenty-five of the patients with abdominal distention were strikingly benefited, the benefit in five was questionable and ten were uninfluenced. Of those with emphysema, all had satisfactory results. Following encephalography the routine use of the method has appeared to prevent severe headaches. It is in severe abdominal distention, such as that which is seen in certain infec-

tious diseases, notably pneumonia, typhoid and peritonitis after abdominal operations, that the method is most useful and at times life saving. It should be considered an emergency measure when simpler means have failed.

Vaccination for Puerperal Infections.—A second series of 177 pregnant women vaccinated against puerperal infections are the subject of the report by Bernstine and Bland. The article dealing with the first series of fifty-one pregnant women so vaccinated was abstracted in THE JOURNAL, March 21, 1936, page 1037. The vaccine consists of five strains of Streptococcus haemolyticus, eight of Streptococcus viridans, two of Staphylococcus aureus, two of Bacillus coli communis, four of Streptococcus nonhaemolyticus and ten of Staphylococcus albus. The respective percentages of these strains in the vaccine are 35, 15, 15, 15, 10 and 10. The patients (228) in both series were delivered with no fatalities. The puerperal morbidity was 5.4 per cent as compared to the morbidity of the nonvaccinated women, which was 19.2 per cent. Ninety male and eighty-two female children were born to the 177 vaccinated patients. There were three abortions and two stillbirths. In the entire group there were three abnormalities—hemangioma of the maxilla, supernumerary digits and left clubfoot. The vaccine was administered to pregnant women with various complications in addition to their pregnant state. These complications varied in type and severity, and yet not a single case was observed that presented an aggravation of the preexisting condition. The patients were not hand picked but represent a cross section of the average obstetric practice with its associated complications.

Pulmonary Tumors in Mice: Parts VI, VII, VIII and IX. H. B. Andervont.—p. 1512.

Induced Malaria in Negroes with Dementia Paralytica.—According to Young and McLendon during the last year, at the South Carolina State Hospital, ten Negro dementia paralytica patients who had been infected for therapeutic purposes with quartan malaria were given mapharsen. Each patient received 0.04 Gm. of mapharsen intravenously weekly for a period of ten weeks. At the same time 0.02 Gm. of thiobismol was given. Subsequently, two of the ten patients received a course of tryparsamide. Twenty-two weeks after the completion of the mapharsen treatment, blood smears from all ten patients still showed parasites (Plasmodium malariae) although the patients showed no symptoms of the disease. To test the viability of the parasites, subinoculations were made from two of the mapharsen-treated persons to two uninfected subjects.

Typical symptomatic and parasitic infections with quartan malaria developed in both, which showed that the mapharsen had not affected the viability of the malaria parasites. Examinations were made of three quartan malaria patients who had received trypanarsamide in antisyphilitic treatment. One year after the completion of the trypanarsamide treatment two patients still harbored *Plasmodium malariae* in the blood stream. Another patient still had parasites nine months after treatment. Another group of eight patients was started on trypanarsamide. Four patients completed the treatment and the malaria parasites were continually present. Treatment of the other four was interrupted after the fifth week, and all had shown malaria parasites continually. Subinoculation from one of this group resulted in a typical symptomatic and parasitic course of malaria, showing that the parasites were still viable. As these drugs relieved the symptoms without eradicating the infection, their use might inadvertently result in quartan malaria carriers being released and thus establish foci of infections of a type of malaria now rare in the United States.

Botulism in Tennessee.—Tucker and Swanson report two cases of botulism, which are of particular interest because for the first time *Clostridium botulinum* toxin was demonstrated to be present in home-canned vegetables in Tennessee. Moreover, for the first time in Tennessee *Clostridium botulinum*, type B, was actually recovered. Twenty cases of botulism in Tennessee which occurred prior to 1939 are reviewed. Home-canned okra and possibly home-canned beans were the foods responsible for the two cases reported.

Trigeminal Neuralgia.—In evaluating the results of hyperpyrexia treatments in trigeminal neuralgia, Schmidt and Sullivan chose typhoid vaccine because of its ease of administration and handling, treating eighteen patients. Injections at about biweekly intervals, starting with a dose of 10,000,000 killed organisms, were given intravenously, and the doses were stepped up by ten or twenty million each time until a good thermal reaction was obtained. Early in their series they learned that results could be obtained as readily with a mild fever response as with a high thermal reaction. The majority of their patients were hospitalized for their treatments, but several ambulatory patients were treated and no ill effects have been encountered. Of five patients more than 80 per cent relief was obtained and they were satisfied to control their residual tic with mild analgesics or Christian fortitude rather than submit to further therapy. Of five other patients, relief was complete and continuous. Four patients experienced complete relief for from two to four months and failed to respond to a second course of vaccine therapy, so that alcohol injections were necessary for the further control of the tics. Three patients obtained 50 per cent relief or less and needed alcohol injections to complete their treatment. Only one patient in the series failed to show some amelioration of symptoms following vaccine therapy; the sensory root of the trigeminal nerve was resected and complete relief ensued. Women showed a slightly better response than men to this form of treatment. Snake venom in a trial group proved unsuccessful in relieving pain of this type.

Density of Bone and Fibrosis of Marrow.—Fairbank lists the principal conditions in which more or less severe generalized osteoporosis, or want of density of the skeleton as a whole, is found: osteogenesis imperfecta, osteogenesis imperfecta cystica, infantile scurvy, rickets, osteomalacia, celiac rickets, idiopathic steatorrhea in adults, renal rickets, renal glycosuria in adults, hyperparathyroidism, osseous dysplasia following icterus neonatorum, thyrotoxic osteoporosis in adults, osteoporosis due to pituitary basophilism, senile osteoporosis and generalized osteoporosis from prolonged recumbency and cachexia. Alterations in the density of the bones are in the direction either of osteoporosis or of osteopetrosis. These two changes may be present in a single case, even in a single bone, there being a tendency in many cases for an initial osteoporosis to be replaced by increased density. The author suggests that marble bones with a limited distribution, generally known as melorheostosis, is really a particular type of diffuse fibrosis of bone. Some evidence is presented that generalized osteopetrosis or Albers-Schönberg's disease, may be similar. The occasional association of cutaneous lesions, usually of a fibrotic nature, with multiple bone changes is commented on. In the etiology of the more obscure disorders it is possible that the parathyroids may be responsible, partly or entirely, for such diverse conditions as renal rickets and marble bones, as well as for the fibrocystic osseous changes of hyperparathyroidism.

Vascular Anomalies of Upper Limbs and Cervical Ribs.—Hill cites a case of bilateral cervical ribs accompanied only by vasomotor disturbances of the hands of the acropara-

type in which removal of a rib and the fibromuscular band relieved pain, diminished swelling and improved the color of the hand on the corresponding side. Other anatomic variations are worthy of consideration in cases of vascular disorders of the upper extremities and, with rational indications, exploratory operation on this region would be warranted.

Gallstones and Cancer.—In order to prove further that chronic irritation is not the cause of cancer, Burrows placed gallstones and other foreign bodies in the gallbladders of fifty guinea pigs, which subsequently lived for periods varying from nine to 359 weeks. In no instance did cancer of the gallbladder develop. These results are regarded as supporting the view that experimentally chronic irritation alone is not the cause of cancer.

Hepatic Insufficiency in Scarlet Fever. R. W. Carslaw.—p. 278.

Rheumatism and Climate.—The literature contains many speculations about the influence on rheumatism of cold and damp, cyclonic disturbances, the electrical state of the atmosphere and the like but Hill states that the evidence shows that it is conditions produced by dirty, artificially heated and poorly ventilated houses and density of population which cause decay of teeth, catarrhal infections and rheumatic troubles. The ill effects of these conditions are intensified by a diet in which the protective foods are deficient. Women suffer from rheumatic troubles more than men, because the latter by going to work change to better conditions. The fear of cold intensifies the ill effects of the indoor environment.

Hepatic Insufficiency in Scarlet Fever.—Carslaw studied 219 cases of scarlet fever in the hope of detecting some warning in those cases in which nephritis developed later. He noticed that there was a general fall in the urea factor throughout the first three weeks of the illness and that the figure was at its lowest at the critical period—that is, at the period when nephritis most commonly occurs; at the end of the third week. The urea factor was found to be lower in the nephritic than in the non-nephritic cases. Therefore the author proposes the determination of the specific gravity of the urine and the percentage of urinary urea as a clinical test of hepatic function. The urea factor can be of value in the prognosis of scarlet fever.

Nicotinic Acid for Delirium Tremens.—Mainzer and Krause state that in a chronic whisky addict an attack of delirium tremens (recurrence) associated with severe gastrointestinal manifestations and acute stomatitis was made to disappear within twelve hours by the administration of 0.6 Gm. of nicotinic acid. Previous to this, thiamin chloride had been given in large doses without any perceptible result. The prompt response to nicotinic acid favors the assumption that lack of this vitamin is an important factor in the development of delirium tremens.

Salt and Water Requirements in Hematemesis and Melena.—Jones examined the postmortem records of seven cases of hematemesis and melena that have ended fatally after hemorrhage had ceased, that is delayed death. An analysis indicates that severe dehydration was the common factor in these cases and that symptoms were masked by the liberal administration of opiates. The dehydration was due partly to insufficient fluid intake and partly to a forced diuresis. The latter was

probably the result of a much increased excretion of urea, presumably derived from the digestion of blood in the intestine. Such patients should receive enough fluid to meet the normal requirements of the kidneys, skin and lungs, and to replace any abnormal fluid loss. In addition, it is recommended that they should be given 10 Gm. of sodium chloride daily during the first few days after the hemorrhage.

Maternal Age and Parity in Placenta Praevia.—Penrose studied the maternal histories of seventy-two cases of placenta praevia. The material collected, together with some additional data, has been analyzed in such a manner as to obtain information about the etiologic importance of maternal age and multiparity. The data suggest that increasing maternal age is a significant factor in producing the central type, though multiparity can be the chief cause in some marginal and lateral cases of placenta praevia. The expected mean maternal age at normal births is seen to be 29.1 years; the observed mean maternal age in all the cases of placenta praevia is 31.86 years. The difference between these two means is of highly significant value in the statistical sense: it is nearly four times the standard error, which is ± 0.71 years. With regard to multiparity the mean birth rank for placenta praevia was 3.55. This value was higher than that of expected normal births, 2.58. The difference of almost one rank between observed and expected values is statistically significant and is nearly as significant as the maternal age difference.

Pathology of Hyperemesis of Late Pregnancy.—In the course of routine work it became evident to Sheehan that the textbook descriptions of the pathologic lesions of hyperemesis or late vomiting were somewhat misleading. A study was made of the thirty-two patients who died and were examined post mortem within the last ten years, adequate histologic material having been preserved. The thirty-two patients died as a direct result of hyperemesis or of vomiting of late pregnancy, either before or within twenty-four hours after delivery. The author points out that the pathologic lesions found in these cases resulted from vomiting and an inadequate diet. There is evidence of loss of weight, but the body is usually not greatly emaciated. The heart is atrophied; the severity of this change is proportionate to the duration of the vomiting. The kidneys frequently show fat in the mitochondrial zone of the first convoluted tubules; this is dependent on acidosis during the last few days before death and is not present if adequate amounts of dextrose are administered during this time. The liver sometimes shows a fatty infiltration which may be centrilobular or, less commonly, periportal. This appears to be due to mobilization of body fat consequent on starvation. The brain, in patients who develop the terminal cerebral syndrome, shows the lesions of Wernicke's encephalopathy. Patients who die as a result of vomiting of late pregnancy do not have atrophy of the heart but otherwise show the same changes as in hyperemesis. In addition, evidence of the etiologic factor, such as pyclitis or hypertensive toxemia, is usually present. Patients who die in the early puerperium after these conditions may continue to show the same lesions that are found in the course of the disease. However, there may be additional changes due to the anesthetic or to puerperal sepsis. From the present investigation and from a study of the literature, it seems probable to the author

that all the cases of hyperemesis or late vomiting that have been reported as showing centrilobular necrosis of the liver were really cases of delayed chloroform poisoning. Certain of the other changes reported in the literature, such as necrosis of renal tubules, are only artefacts produced by postmortem autolysis. That the liver or kidneys may show any grade of the development of degeneration or necrosis out of the fatty change does not rest on any satisfactory foundation.

Etiology and Treatment of Hyperemesis Gravidarum.

—In discussing the pathogenesis of hyperemesis, Bandstrup sums up present knowledge by stating that, owing to some unknown cause, the woman begins to vomit. The further course of the illness may depend to a large extent on psychic factors. A state of inanition develops, of which want of glycogen in the liver is probably the most serious feature even though the want of salt, water and vitamins, together with the development of acidosis, is an important factor. A specific toxin of hyperemesis has never been demonstrated as a cause of the necrotic changes in the liver and other organs, and it is not inconceivable that these changes may develop as a result of the inanition under the special endocrine conditions present in pregnancy. In keeping with his view of the pathogenesis of this disease, his treatment consists of psychic, sedative and restorative therapy; if this is found inadequate pregnancy has to be interrupted. The psychic therapy consists of a firm suggestive management on the part of the physician and admission to a hospital, possibly with isolation of the patient. Sedatives, such as bromides and barbituric acid, have a calming effect on the mind of the patient and lower the irritability of the center for vomiting. The restorative therapy consists in the administration of dextrose, insulin, sodium chloride, water and vitamins. The future will show whether adrenal cortex extract is to be established as an effective remedy in the restorative therapy. If conservative treatment on these principles fails to lead to recovery, it may be necessary to induce abortion. Seven symptoms are considered as indications for interruption of pregnancy in hyperemesis. These symptoms include elevation of the temperature above 100.6 F. or persistent subfebrile temperature, persistent increase in the pulse rate over 100 a minute, jaundice, albuminuria, polyneuritis, ocular symptoms and psychotic changes. From a study of forty fatal cases of hyperemesis, twenty-five presented only one or more of the foregoing serious symptoms for more than one week prior to interruption of pregnancy or death. So the mere presence of one serious symptom has to be taken as a warning. All the patients were admitted to the hospital, even though a few of them did not enter the hospital till immediately before death. The treatment, as a rule, consisted of restorative and sedative treatment, besides therapeutic abortion in thirty of the forty cases.

Encephalomyelitis After Sulfanilamide.—Fisher cites two cases in which symptoms of encephalomyelitis appeared after the administration of small quantities of sulfanilamide. The total doses taken were small (14 and 18 Gm., respectively) and if the drug was responsible the patients must have been more

than ordinarily susceptible to it. There is evidence in patients suffering from certain illnesses—including acute rheumatic fever and lupus erythematosus—in which toxic manifestations after taking sulfanilamide are especially likely to develop. Vascular changes are seen in some cases of encephalomyelitis and their relation to the demyelinating lesions is discussed.

Tissue Anoxia and Its Treatment.—Poulton calls attention to the fact that the importance of local tissue anoxia and its treatment with oxygen has not been recognized heretofore, except that success has been claimed for oxygen therapy in varicose ulcer with local edema, poisoning with alcohol and coronary thrombosis. The inhalation of a high percentage of oxygen may have a wide application in treatment; its use in cerebral hemorrhage, thrombosis and embolism is suggested. The evidence that there is local anoxia in rheumatic myocarditis is a changed lactic acid metabolism and clinical improvement on treating patients with oxygen, resulting in a fall of temperature and pulse rate, alteration of murmurs, diminution in the size of the heart and electrocardiographic changes. Oxygen treatment in early cases appears to be of permanent benefit, but further observations are required. In seventeen of twenty-six rheumatic patients (fifteen in their first attack), treated with oxygen for periods varying from about a week up to eighty-two days clinical improvement was noticed. The patients felt better; they were more active and ate more and cyanosis disappeared; one could "breathe better." The improvement was most obvious of extremely ill patients, such as one with pericarditis, nephritis and purpura, who was so ill that oxygen had probably saved his life, another who had made but little recovery from a pericarditis and one with pneumonia and pericarditis. All these were children. Improvement was noticed whether the acute rheumatism was a first attack or accompanied by an old standing cardiac lesion. Adult patients also felt better. In eight cases there was no clear subjective improvement. A patient who had an enlarged cardiac shadow which indicated pericarditis did well in the tent, but the value of prolonged treatment was not realized as he was taken out of it after two days. Two and a half months later he was put in the tent for thirty-five days; there was massive edema, scanty urine and an enlarged liver; he died soon after being taken out of the tent. Hence oxygen should not be left till the last stages of rheumatic heart disease. A control series of sixteen cases observed over the same period tells a different story. In two cases in which there were systolic murmurs the cardiac condition cleared up in less than a month in one and in eleven weeks in the other. Another patient began with nodal rhythm, ventricular escape, and pre-systolic and systolic murmurs; after two months there were a systolic murmur and good first sound, and the pulmonary second sound reduplicated on inspiration. These three results are good. The results in the remaining thirteen are poor: in two cases soft systolic murmurs appeared and have persisted for nearly nine months in one and more than two months in the other, in two there were loud systolic murmurs and weak first sounds, in five middiastolic murmurs or their equivalents remained, in two there remained aortic diastolic murmurs and in two there was tachycardia, with a late blowing systolic in one.

Anahemin for Nutritional Macrocytic Anemia.—Foy and Kondi find that the nutritional macrocytic anemia seen in Macedonia responds as readily to anahemin as to less purified liver extracts. This response is in contrast to the cases treated in India and suggests that the Macedonian cases differ from those in India, in which a high indirect van den Bergh reaction is rare. glossitis is common and the highly purified liver preparations are inactive. Such responses to these highly purified extracts make it appear unlikely that the filtrate factor of Edgar and Macrae is the active one in the cure of nutritional macrocytic anemia in Macedonia. Further, work done with the filtrate-factor concentrate shows that this, administered alone, is inactive

even when given in large doses. It is not impossible that the response to anahemin is quantitative and related to the liver content. It is active in 2 cc. doses and will probably be found active in smaller doses. Although the quantitative aspect is important, it is probable that the qualitative aspect also enters into the picture, for work now in progress seems to show that large amounts of filtrate combined with small amounts of anahemin are extremely active. This work suggests that the conclusions drawn by Wills and Evans (1938) and Napier (1939) do not apply to the nutritional macrocytic anemia of Macedonia as typical responses to anahemin were obtained. Further, the suggestion that there is some active principle present in the filtrate factor is not borne out by work with filtrate-factor concentrates, which do not produce any effect on the anemias in Macedonia. Such observations appear to bring back the position to that originally postulated by Castle.

Sodium Diphenyl Hydantoinate for Epilepsy.—Blair and his colleagues used sodium diphenyl hydantoinate in the treatment of fifty-three male and twenty-two female epileptic patients having grand mal attacks. Fifty-eight of the patients have been treated continuously for from two to six months, in eleven it was necessary to terminate treatment and six recently admitted patients have not yet received two months of treatment. The authors' results confirm those of Merritt and Putnam, that the drug is a strong anticonvulsant, its action sometimes being dramatic, but a weak depressant. Apart from the reduction in the number of fits, the drug was beneficial to the mental condition of many patients. In patients having chronic psychotic epilepsy there was little room for intellectual improvement, but a beneficial modification of the typical epileptic temperament was often observed. Most of the patients improved mentally, being more cheerful and congenial, less quarrelsome and complaining and more easily managed and occupied. In some cases the effect has been remarkable. Detrimental changes may, however, develop in association with toxic effects, and whenever a patient's mental condition appears worse, chronic poisoning should be suspected. Many patients exhibited toxic nervous symptoms, but a rash developed in only one. These toxic symptoms often developed after an increase in the dose.

Malnutrition and Debility in Puerperal Psychoses.—

It is generally accepted that there is no specific form of mental disorder associated with childbirth and that when mental illness begins during pregnancy, the puerperium or lactation, childbirth may act as a precipitating factor. However, Haworth asserts that during childbirth there are certain points worthy of consideration. First the mental illness of pregnancy is often associated with some other contributory cause. Many of these women have already had one or more confinements and many of them pass normally through later confinements. This suggests that some other factor of a temporary nature is involved. The most important thing in the study of these contributory causes is the recognition of those which might be eliminated. Some, such as hereditary predisposition and lifelong nervous instability, cannot be removed, but a knowledge of their presence in the early days of pregnancy should suggest a special effort to build up the general powers of resistance and to eliminate additional preventable factors. Of the preventable contributory causes the author suggests that the two most important are (1) malnutrition and general debility and (2) stress and anxiety, emotional or environmental. The admittance of 117 cases of mental illness arising in connection with childbirth to Severalls Mental Hospital over a period of fifteen years shows how common these factors are. All but six patients were admitted dur-

ing the late months of pregnancy, during the puerperium or during lactation. In every case this was the first occasion on which the patient had been admitted to a mental hospital; seventy-two of the patients recovered, sixty had already had one or more normal confinements and twelve have had one or more confinements since their discharge from the hospital without developing any mental symptoms. Fifty-four of the sixty-eight women weighed on admission were below normal weight, twenty-eight being more than 14 pounds (6.4 Kg.) underweight. In every case except one, recovery was associated with an increase in weight. Only twenty-eight of the 117 patients were found to be in satisfactory general health when admitted to the hospital, none of these showing any sign of physical disorder. The majority were suffering from minor physical ailments, eighty had dirty, furred tongues and were and had been suffering from constipation, sixty had carious teeth or pyorrhea or both, thirty-two were suffering from anemia and, as has been shown, many were poorly nourished and underweight. A history taken in the early days of pregnancy would have shown that thirty-six of these patients belonged to families in which a near relative had suffered from insanity, epilepsy or alcoholism, twenty-nine had at some period in their life already shown signs of nervous instability, while twenty-two had undergone long and severe stress. Therefore it seems that many instances of puerperal psychosis could probably be prevented by attention to nutrition, general health and environmental conditions early in pregnancy.

After-Effects of Exposure to Carbon Dioxide.—According to Alexander and his co-workers, after breathing air with a partial pressure of more than 6 per cent of carbon dioxide for an hour or longer, five of six men experienced headache on breathing oxygen and two of them vomited. The bearing of this observation on escape from submarines is discussed and it is suggested that in such circumstances men should breathe air or oxygen for thirty minutes or more before attempting to use the escape apparatus, because under these circumstances vomiting would prove fatal and calmness and some physical exertion are required.

Heterologous Antibodies in Poliomyelitis Serum.—

Burnet and his associates postulated that poliomyelitis in human beings is strictly confined to the central nervous system and that extremely little antigen reaches any part of the antibody-producing mechanism. If this is so, poliomyelitis antibody must be either the response to another antigen having determinant groups in common with poliomyelitis virus or a change in the serum globulin content, associated with increasing age or increasing experience, or both, of a variety of antigenic stimuli. To come to a decision between these alternatives, they investigated a series of samples of serum from seventy patients with poliomyelitis for their content of four antibodies in addition to poliomyelitis antibody: diphtheria antitoxin, herpes simplex virus, swine influenza antibody, which was included because of its curious behavior in relation to age (it appears only in individuals more than 10 years of age), and staphylococcus α antitoxin. The results have been analyzed according to age and social environment and compared with those from control groups. There is no different proportion of any of the heterologous antibodies in these specimens of serum than would be found in a comparable group of normal serum specimens. Herpes simplex antibody and diphtheria antitoxin are both much more frequently found in children from crowded industrial suburbs than in those from better class areas. In the industrial areas herpes infection is contracted before the age of 2 years, while diphtheria antitoxin appears as a rule only after the child has begun to attend school.

There is no association between the frequency of swine influenza antibody or staphylococcus antitoxin in serum and the nature of the social environment. There is a significant correlation between the presence of poliomyelitis antibody and diphtheria antitoxin in young children from industrial suburbs; this suggests that the two antibodies are acquired at about the same age and under similar environmental conditions.

Acetone of Urine in Pulmonary Tuberculosis.—Yamazaki decided to investigate the disturbances in the carbohydrate and fat metabolism of patients with pulmonary tuberculosis. He determined the elimination of acetone in the urine and compared it with that of healthy persons; he also studied the changes in the acetone content of the urine following tolerance tests with fat. The studies were made on 101 patients with pulmonary tuberculosis and on six healthy persons. He found that with healthy persons the urinary elimination of acetone averages 12 mg. daily. In cases of pulmonary tuberculosis it was higher, the daily average being 16.87 mg. On the whole, the acetone value was the higher, the more severe was the tuberculous process; that is, there was a parallelism between the type and stage of the disease and the urinary elimination of acetone. A comparison of the acetone values in the cases in which a diet with a high fat content was administered with those in cases in which such a diet was not given disclosed higher values in the first group. In cases in which glycosuria developed following the intake of large quantities of fat the acetone values were extremely high. Fat tolerance tests of healthy persons increased the acetone content of the urine on the average by 12.7 per cent; fat tolerance tests of patients with pulmonary tuberculosis and glycosuria produced an increase of 34.2 per cent. The author further shows that in cases of pulmonary tuberculosis the increase in the acetone content goes parallel with the height of the temperature and with the sedimentation speed of the erythrocytes.

*Management of Labor and Prognosis for Child in Breech Presentation in Old Primiparas. J. Snoeck and R. Canon.—p. 1272.

Breech Presentation in Old Primiparas.—Snoeck and Canon show that the opinions regarding the prognosis of breech presentation in old primiparas and regarding the management of such cases differ greatly. They reexamined this problem on the basis of observations made in the years 1927 to 1938 at the maternity clinic of the University of Brussels. They present two series of eleven cases each. In one group of eleven cases the so-called classic methods were employed and the results for the fetuses were disastrous, the fetal mortality being seven. In the second series of eleven cases of breech presentation in old primiparas, the method of treatment was the low cesarean operation. In all these cases mother and child were entirely well when they were discharged from the clinic. On the basis of the comparison of the results obtained in these two series of cases, the authors conclude that the low cesarean operation is indicated in "dystocic" breech presentation of primiparas over 30 years of age. They list the conditions which signify "dystocic" breech presentation in an old primipara and which indicate cesarean operation as follows: (1) all breech presentations combined with narrow pelvis in which the true conjugate diameter measures less than 10.5 cm. so far as the presentation remains mobile within the limits of time specified later; (2) all breech presentations, whatever the true conjugate diameter may measure, which do not become engaged during the first ten to fifteen hours of labor, and this without taking account of the time of rupture of the bag of waters; (3) all breech presentations which are engaged before this lapse of time and in which the progression is slow or null in spite of two or three hours of good uterine contractions; (4) all breech presentations with anomalies of the uterine contractility or of the dilatation of the cervix, when these do not yield rapidly to energetic medical treatment. The authors think that all old primiparas should be delivered in an obstetric clinic. Regarding the technic of the treatment, they say that the low cesarean operation must be entirely segmental and not corporeal or corporeosegmental. They think that the transverse section of the muscular layer of the inferior segment is the only technic which guarantees the integrity of the body of the uterus in case of further tearing of the surgical incision.

*Covered Perforation of Gastric and Duodenal Ulcer. H. Gjankovic.—p. 1263.

Covered Perforation of Gastric Ulcer.—Following a review of the literature on closed perforations of gastric and duodenal ulcers, Gjankovic discusses the clinical aspects of these types of perforations and gives rules regarding their treatment. In the second part of the paper he describes his personal observations. Among 109 cases of perforated gastroduodenal ulcers treated by him he encountered thirteen perforations that were covered (11.92 per cent). All except one of these covered perforations concerned duodenal ulcers, which indicates that covered perforations are much more frequent in duodenal than in gastric ulcers, even if the higher incidence of duodenal ulcers (sixty-nine of the 109) is taken into consideration. The author thinks that the prognosis of covered perforations is generally favorable but is doubtful until definite cure is established. Although spontaneous cure is possible, surgical treatment is indicated in all cases. If the perforation is recent it is necessary to operate immediately, except that the indication should be ruled by the clinical syndrome, the stage of the disease and the condition of the patient. Of the various surgical methods the resection is always indicated in the covered perforation of gastric and duodenal ulcer if there is no general contraindication. If on the other hand there is one, it is necessary to limit the operation, according to the nature of the contraindication, to a suture (if this is practical) with primary suture of the abdominal

wall. Conservative therapy is permitted only in a clinic, where permanent and competent control is possible. The circumscribed secondary abscesses with localized peritonitis should be opened and drained immediately under strictly aseptic conditions. The sutures of the covered perforations of the stomach and duodenum as well as anterior or posterior gastro-entero-anastomosis give the best permanent results in 75 per cent of the cases. The same results can be obtained by resection. The latter has advantages, because it readily and probably forever excludes late complications which may develop subsequently with the conservative operations. Therefore resection is advisable in all cases of covered perforation except for certain contraindications.

*Function of Bone Marrow in Nephritis. B. Nolli.—p. 1023.

Tables with Clinicolumbar Dissociation: Histopathologic Study of Case G. Fattovich.—p. 1050.

Calcification of Nucleus Pulposus: Cases. L. Pinelli.—p. 1073.

Bone Marrow in Nephritis.—Nolli says that early in the development of nephritis a myelopathy develops which causes nephritic anemia. The author studied the functions of the bone marrow in eighteen cases of nephritis of various types and at different evolutionary stages. The observations were made on medullary blood which was taken by sternal puncture. The author found that the changes of the myelogram, of the leuko-erythropoietic ratio in the myelogram and of the curves of maturation of the stem blood cells of both the erythroblastic and the leukoblastic series, in renal sclerosis with anemia from old age, are those which correspond to hypoplasia of the bone marrow. In acute diffuse glomerulitis as well as in acute hemorrhagic glomerulitis with anemia the medullary alterations are of the type of those which are observable in acute and subacute forms of posthemorrhagic anemia. However, erythrocytes in the peripheral blood show morphologic alterations which are characteristic of nephritis. In diffuse chronic renal inflammation the hematopoietic functions (output of stem cells) are diminished. The leuko-erythropoietic ratio in the myelogram is disturbed with predominance of either myeloblasts or erythroblasts from uneven formation of the cells, the curves of maturation of the cells are increased, mitosis is diminished and the medullary threshold for passage of mature cells to the blood is increased. The myelopathy causes typical alterations to the peripheral blood with morphologic changes of the erythrocytes and diminution of their number. Its evolution parallels that of the renal disease and it progresses to aplasia of the bone marrow. Administration of a combined treatment of arsenicals, iron and liver extract, early in the development of the renal disease, controls the functional disorders of the bone marrow with consequent control of the morphologic changes of the blood cells. The medullary alterations of nephritic myelopathy are different from those which are seen in the various forms of myelopathy in secondary anemia of toxic or infectious origin. They are also different from those which develop in anemia from insufficient supply of minerals in the diet and from pernicious anemia. In the terminal stages of the renal disease as well as in true uremia the bone marrow is transformed into a gelatinous yellow material which does not contain any active red marrow.

Surgical Treatment of Acute Infections of Fingers and Hands. E. Andreón.—p. 567.

Neurolymphogranulomatous Syndromes.—Plá and his collaborators say that malignant lymphogranulomatosis may cause various types of nervous syndromes from compression of the lateral columns of the spinal cord, the brain or the nerve roots by lymphogranulomatous lymph nodes or their metastases. Certain nervous syndromes may also be observed in absence of nervous compression. The authors report two cases. In the first case a syndrome of diffuse meningo-radicular neuritis developed in the course of the disease with paralysis of the sixth nerve, oculosympathetic paralysis (Horner's syndrome) and radicular sciatic pain. In the second case, also in the course of the disease, a form of progressive bilateral muscular atrophy

of the extremities developed. In both cases the Wassermann reaction of the blood and cerebrospinal fluid was negative, there were no symptoms of tumors or tumoral compression at the brain or the spinal cord, and the cerebrospinal fluid, taken by spinal puncture, showed the presence of a meningeal reaction of irritation. In the second case paralysis and sensory disturbances did not exist and the iodized poppyseed oil did not stop after having been injected by the suboccipital and lumbar routes in the Trendelenburg position. The authors conclude that in both cases the nervous symptoms were caused by the lymphogranulomatous virus, which was located at the meninges and various nerve roots in the first case and at the lateral columns of the spinal cord in the second case. The development of nervous syndromes in malignant lymphogranuloma in the absence of nervous compression prove, according to the authors, the existence of lymphogranulomatous virus, although it has not yet been identified.

Hepatic Function During Sulfanilamide Therapy.

According to Schmidt, the administration of chemotherapeutic substances taxes the intermediate metabolism and particularly the liver. He also raises the question as to which toxin is more likely to cause damage, that of the infection or that of the chemotherapeutic substance. In this connection he cites observers who described cases of gonotoxic icterus and then describes his own studies on the hepatic function of gonorrheal patients who underwent treatment with sulfanilamide. In twenty-nine cases he tested the hepatic function before, during and after the administration of sulfanilamide by means of the galactose tolerance test according to R. Bauer; simultaneously he observed the blood sugar curve and examined the urine for urobilinogen, tyrosine and leucine. He found that the functional examination of the liver of patients with gonorrhea often revealed pathologic values, before treatment with sulfanilamide was instituted, and that the administration of sulfanilamide nearly always exerted a favorable influence on the hepatic function. In cases in which the hepatic function was normal before the administration of sulfanilamide, no damage was observed after this medication. Moreover, gonotoxic icterus rapidly disappeared under the influence of sulfanilamide. A comparatively large dose of sulfanilamide (63 Gm.) caused no hepatic impairment in the author himself. In two cases of severe intoxication with a nitrosulfanilamide body, the test of the hepatic function disclosed no impairment of the hepatic parenchyma. Chemotherapy by means of sulfanilamide preparations never resulted in urobilinogenuria, nor were tyrosine and leucine ever detected in the urinary sediment during or after the sulfanilamide treatment. The author concludes that these results demonstrate the indifferent behavior of the examined sulfanilamide bodies toward the hepatic parenchyma.

Surgical Treatment in Congenital Muscular Torticollis.

—Koch considers in this report only cases of true congenital muscular torticollis, disregarding the cases of torticollis resulting from primary bone changes and also those mild cases of torticollis in which exercise and massage counteract the slight contraction of the sternocleidomastoid muscle. Regarding the

surgical technic employed at his clinic, he says that a cutaneous incision 2 cm. in length (usually longitudinal) is made above the lower end of the sternocleidomastoid muscle. Then follows exposure and division of the sternal and clavicular heads of the muscle and division of the surrounding fascia, also detachment of all shortened fascial strands. In a few cases from 1 to 1.5 cm. of the muscle is removed. Following arrest of hemorrhage and cutaneous suture, Schanz's absorbent cotton bandage is applied and the patient's head is fixed in a position which overcorrects the deformity. The bandage is renewed after eight and twenty-four days, and after an additional three weeks the last bandage is removed and then passive exercises and massage are begun, which are continued for from six to twelve months or longer. In order to obtain information about the efficacy of this method, the author made inquiries regarding 117 patients who received this treatment during the years between 1930 and 1937 inclusive. Information was obtainable from 108 of these patients. At the time of operation the patients varied in age between 4 months and 18 years. In 61 per cent of the patients the operation was performed during the first two years of life. Summarizing the results, the author says that in eighty-six cases the results were good, in twenty-one cases were unsatisfactory and in one case were bad. He emphasizes that the best results were obtained in those cases in which the operation was performed during the first two years of life.

Surgical Treatment of Severe Static Flatfoot.—Pavlik says that the severest forms of flatfoot, which are characterized by curvature of the leg, especially in the distal portion just above the ankle joint, and which present subluxation in the talonavicular joint, abduction of the anterior part of the foot, valgus position of the heel and contracture of the extensors, of the peroneal muscles and of the achilles tendon, require surgical treatment because conservative treatment fails to produce the desired results. The author describes three different types of surgical treatment which are designed to correct the various forms of flatfoot. He shows that it is necessary to select that type of surgical method which, on the one hand, reconstructs the arch of the foot and, on the other hand, counteracts the curvature of the lower part of the leg, which is the essential cause of the collapse of the arch of the foot and of the subluxation in the tarsal joints. If the curvature in the leg is removed, the crural skeleton becomes shorter and the muscular contracture, which together with the arthrosis deformans-like changes in the talonavicular joint causes the deformity of the foot, subsides. The author resects the talonavicular joint by removing the cartilage and the arthrosis deformans-like changes from the head of the talus. By osteotomy of the bones of the leg he overcomes the curvature and by suitable wedge-shaped osteotomy of the tibia causes the reposition of the subluxation in the talonavicular joint to become possible.

*Resistance and Immunity in Tuberculosis. L. Ascher.—p. 71.

*Iodine Therapy in Hypertension and Arteriosclerosis. N. Alwall.—p. 83.

Resistance and Immunity in Tuberculosis.—Ascher directs attention to the age law of natural, internal resistance, which was formulated by him many years ago. According to this law the general, internal and natural resistance increases from infancy to school age, reaching its maximum between the ages of 5 and 15 years, and then it decreases with advancing age. The author cites statistical reports on tuberculosis from different countries. He points out that unfavorable nutrition increases the mortality from tuberculosis, whereas reduction in industrial activity reduces the mortality rate from tuberculosis. It has been demonstrated that in times of economic crisis, with unemployment, the mortality from tuberculosis decreased further than it did during times of prosperity and employment. Moreover, this decrease in mortality was limited to the employed age groups, whereas in children there was a slight

increase in mortality. The author further gives his attention to immunity and says that in some large cities 100 per cent of the adults give a positive Pirquet reaction. Approximately 0.5 per cent of these develop tuberculosis annually; that is, 0.5 per cent of the immune persons develop the disease, not 0.5 per cent of the infected ones. The author emphasizes that the activity of the tubercle bacillus is limited by the natural internal resistance of the human organism and by the immunity produced by the bacillus itself. However, resistance and immunity are subject to impairment and consequently are not always complete. Factors which play a part in this impairment are nutrition, exertion and exposure. After discussing these, the author says that the reduction of the tuberculosis mortality hitherto has been examined only from the point of view of medical and social measures. He shows that spontaneous, that is, endemically acquired, immunity is the main factor, at least in regions where and in times when no measures are taken against tuberculosis, and when its mortality has been known to decrease more than at times when measures were taken against it. The comparative freedom of children of school age from tuberculous manifestations in the presence of slight individual infection, but of approximately 50 per cent positive Pirquet reactions, indicates adequate immunity in the concurrence of highest resistance with small quantities of infectious agent. There is the possibility of improving the immunity by BCG. Since it is possible that the time may come when the population will not acquire an adequate immunity in the spontaneous manner, immunizatory measures, as in the case of smallpox, might have to be employed.

Iodine Therapy in Hypertension and Arteriosclerosis.—Alwall points out that iodine is widely recommended in the treatment of vascular diseases, particularly arteriosclerosis and hypertension. The generally accepted opinion is that iodine reduces the viscosity of the blood and consequently the resistance to the current, thus facilitating the circulation. This opinion was supported by earlier experiments, which demonstrated that the viscosity of the whole blood decreases under the influence of iodine therapy. More recent experiments demonstrated, however, that the viscosity of the plasma and not the viscosity of the whole blood determines the resistance to the blood current. For this reason the author reports his investigations on the question whether the viscosity of the plasma is influenced by iodine therapy. He examined the plasma of healthy persons and of persons with hypertension by means of Hess's viscosimeter. He made these tests before iodine therapy was instituted and after it had been continued for shorter or longer periods. The iodine therapy was found to produce no changes in the viscosity of the plasma and the author thinks that this contradicts the old theory that iodine therapy reduces the resistance to the blood current by lessening the viscosity and thus facilitating the circulation. He suggests that there must be another explanation for a possible favorable action of iodine therapy on arteriosclerosis and hypertension.

*Mortality of Lupus Vulgaris Patients and Cause of Death. C. X. S. Gundtoft.—p. 832.

Cause of Death in Lupus Vulgaris.—Gundtoft studied the cause of death in 211 cases of lupus vulgaris (sixty-five men, 145 women) treated at the Finsen Institute during the last twenty-five years. Only three patients, all advanced in age, died from lupus itself, sixty-one (twenty-one men, forty women) died from pulmonary tuberculosis, four men and seven women died from tuberculous meningitis, nine men and seven women died from tuberculous diseases other than those mentioned and about half the patients died from causes not connected with tuberculosis. Lupus vulgaris is, thus regarded as a benign disease but one which calls for careful examination as to the possible coexistence of tuberculous processes elsewhere.

THE TREATMENT OF RETRODISPLACEMENTS OF THE UTERUS

WALTER T. DANNREUTHER, M.D.

NEW YORK

The term retrodisplacement is used clinically to include both retroversion and retroflexion, although literally it implies a backward dislocation of the uterus irrespective of its relation to the vertical plane of the pelvis. A retroflexion differs from a version only in the break in alinement at the cervicocorporeal junction, and a distinction between the two is of only academic interest. Both alterations in position may be congenital or acquired; neither causes symptoms per se, and their treatment is identical. Retroversionflexions complicated by prolapse in the axis of the vagina constitute a separate problem and are not under consideration.

Congenital displacements are identified in most cases by the foreshortened anterior cervical lip and anterior vaginal fornix, a general hypoplasia of the internal pelvic organs, and the limited mobility of the uterus despite the absence of restraint from adnexal inflammatory involvements. They are frequently associated with endocrine derangements and discovered incidentally in young women who present themselves because of dysmenorrhea, menstrual irregularities or sterility. Such patients seldom complain of sacral backache, the chief symptom attributed to a retrodisplacement. On the other hand, in cases in which the lesion is acquired as a sequel of abortion or labor the symptoms commonly ascribed to the malposition do not appear until after the lapse of considerable time. Hence it is logical to assume that uncomplicated retrodisplacements do not produce symptoms; if they did, there would be a simultaneous symptomatic onset with the backward dislocation, and all patients with defects which have existed since birth would have sacral backache, leukorrhea or other local annoyances. The factors responsible for normal uterine poise and position are the dynamics of the intra-abdominal pressure exerted against the posterior surface of the corpus, the tonicity of the supporting ligaments and the integrity of the perineal musculature. Impairment of any or all of them may eventuate in an acquired retrodisplacement. When one sees patients with displacements that might have been prevented, ill fitting pessaries inserted upside down or back to the front or both, operations performed with failure to relieve symptoms notwithstanding a satisfactory anatomic end result, and recurrences after

laparotomy, it is evident that the subject under discussion has not yet been worn threadbare. It therefore seems pertinent to emphasize the importance of differential diagnosis, to clarify the treatment indicated for various cases, to stress the therapeutic value of the much abused and often neglected pessary and to consider a few effective surgical procedures for patients in whom operation is really indicated.

Having recognized a retrodisplacement, it then becomes important for one to ascertain whether the malposition is congenital or acquired, whether the uterus is replaceable or immobilized and whether or not there is coexisting endocervicitis, parametritis, peri-uterine fixation, adnexal disease or pelvic tumor. All of these modifications have a direct bearing on subsequent treatment. Developmental defects require no corrective therapy. A replaceable uterus may be treated expectantly, with a pessary or by operation. Immobilization is usually due to associated pathologic conditions but is occasionally caused by the incarceration of a large corpus beneath the promontory of the sacrum. If, despite the absence of adnexal disease or pelvic adhesions, bimanual reposition is impossible with the patient in the lithotomy position, it can sometimes be accomplished by a change to the knee-chest position. Instrumental repositors are unnecessary and dangerous. A freely mobile retrodisplacement is often erroneously regarded as uncomplicated simply because no grossly apparent complications can be detected, although there may be intense concomitant passive congestion. In fact, it is the insidious onset of circulatory stasis, particularly in the broad ligament veins, that is responsible for the delayed and gradual appearance of symptoms in the majority of cases. With the uterus in normal position, the uterine and ovarian vessels are widely patent; when retroversion occurs, lateral torsion on their longitudinal axis with consequent narrowing of their caliber is inevitable. As the vascular engorgement increases, the walls of the veins weaken to such an extent that actual varicosities may be seen at the operating table. This is the explanation for the paradoxical initiation of symptoms in cases of "uncomplicated," or easily replaceable, retrodisplacement.

Of the many complaints credited to retrodisplacement only three, sacral backache, a sense of pelvic heaviness and leukorrhea, are apt to be manifestations of the malposition itself. There are so many additional causes of these, as well as of the other pelvic complaints sometimes ascribed to the retroversion, that the mere existence of a displacement by no means justifies the assumption of direct cause and effect. In many instances the cause will be found elsewhere (table 1).

If a sacral backache can be relieved by such measures as unloading an obstipated colon, treatment of posterior parametritis, fitting flat feet with suitable plates, cradi-

cation of remote foci of infection and orthopedic treatment to remedy abnormalities in the lower part of the spine even though a displacement persists, the time to discover this is before a futile laparotomy and not afterward. In other words, the major problem is not the recognition of a retrodisplacement but the differential diagnosis of the true source of the symptoms attributed to it.

A retrodisplacement may be treated prophylactically, expectantly, palliatively or surgically. Proper precautionary measures following abortion, labor and vaginal operations involving traction on the cervix will prevent many acquired malpositions. After therapeutic abortion, packing the uterus with iodoform gauze for forty-eight hours and administration of 1 cc. of solution of posterior pituitary twice daily for three days will hasten involution. After delivery, perineal lacerations should be repaired immediately to restore the integrity of the perineal musculature. Elevation of the patient's shoulders on the second day promotes free lochial drainage. Assuming the prone position for five or ten minutes several times each subsequent day facilitates forward gravitation of the uterus and exertion of the intra-abdominal pressure on the proper fundal area. Deep breathing exercises in the knee-chest position during the third and fourth postpartum weeks help to prevent diastasis of the abdominal muscles and also tend to throw the corpus forward.

TABLE 1.—Symptoms Often Attributed to Retrodisplacements of the Uterus

Symptom	Usual Cause
Sacral backache	Overloaded sigmoid and rectum, posterior parametritis, flat feet, focal infection, sacro-iliac joint, low spinal abnormalities
Menorrhagia	Passive congestion, endometrial alterations, tumors
Leukorrhea	Endocervicitis, endometrial hyperplasia, trichomonas vaginitis
Pain	Inflammatory products in the pelvic structures
Pelvic dragging	Cystocele, rectocele, subinvolution
Dyspareunia	Uterine or adnexal fixation, prolapse of ovaries
Repeated abortion	Incarceration, constitutional disease, endocrine dysfunction
Sterility	Husband, tubal disease, endocrine derangements, endocervicitis

Regular and continued breast feedings reflexly stimulate pelvic involution and should be urged for this as well as other reasons. If all patients are reexamined three, six and twelve weeks after abortion or parturition, retrodisplacements will be detected promptly. It is axiomatic that the farther back the cervix, the farther forward the corpus. Hence the importance of replacing the uterus bimanually and holding the cervix back in the pelvis with a strip gauze vaginal pack, pressed firmly against the portio, after operations such as curettage and trachelorrhaphy, which necessitate pulling the uterus into the vaginal plane.

In addition to congenital displacements which can be safely ignored, some freely mobile retroversions of long standing are found to be symptomless and to require no treatment. Under these circumstances it is wise to request the patient to return for semiannual examinations. On the other hand, if such a displacement is of recent origin, one year or less, the uterus should be held in its normal position for several months with a pessary and not treated expectantly, because the supporting structures may still be capable of regaining their tonicity.

Palliative therapy resolves itself into the application of a pessary in cases of replaceable retrodisplacement, and the treatment of coexisting parametritis and adnexal disease when the uterus is thereby immobilized. The induction of local depletion and hyperemia by such means as strip gauze and glycerin vaginal packing, hot saline douches, sitz baths, diathermy and short wave therapy will oftentimes convert a fixed displacement into one that is replaceable. When the malposition is discovered early it can be corrected with an excellent prospect of a nonoperative cure; in other cases relief is experienced only so long as the pessary is worn. There are four types of pessary well adapted to the treatment of retroversion under slightly different conditions: the Hodge, the Albert Smith, the Thomas and the Findley, of which the Smith is the most popular. The purpose of a pessary is not to correct a displacement but to maintain proper uterine poise after the uterus has been replaced. Incidentally, it serves to demonstrate that permanent anteversion will relieve the symptoms. Certain prerequisites are essential: The bladder should be emptied by catheter, the mobile uterus must be replaced bimanually, there must be no associated prolapse or extensive cystocele, and before an appliance is selected for an individual patient the size and configuration of the vagina should be estimated. The length is determined by inserting the fingers high in the posterior fornix, just as though measuring the diagonal conjugate diameter of the pelvis. The approximate width is estimated by separating the finger tips at the midportion of the vagina. It is thus easy to select a pessary of the size and shape that the patient needs. Misused, misfitted and misapplied pessaries will cause distress and local soreness, whereas one that is fitted accurately can be worn with perfect comfort, if it is removed, cleaned and replaced every six weeks. Every curve in a pessary is designed for a definite reason, and once the principles of construction are understood there is no difficulty in making a selection for an individual patient.

The uterus having been replaced in its normal position, the only thing necessary to keep it there is some mechanical contrivance to hold the cervix back. If two fixed points, the pubic arch and the posterior vaginal fornix, are kept widely separated by a rigid bar or straight stick, the cervix can move up and down through a small arc but cannot come any nearer the vaginal orifice. If a straight stick were used; however, the posterior tip would push sharply into the fornix, so the end must be bent upward to conform to the outline of the fornix and put the uterosacral ligaments on the stretch. Provision having been made for the curve of the vaginal vault, it becomes necessary to make a shorter reverse curve in the anterior end, to allow for the upward pressure of the perineal musculature. This long upward curve permits the pessary to lie up out of the way in the narrow part of the pubic arch. Since the vagina is a wide canal, it is necessary to place another stick with identical curves parallel with the first and to connect the two anteriorly and posteriorly. The posterior bar is wider because the fornix is roomy, the anterior bar narrower so that it can lie well up behind the pubic arch. The little transverse notch and downward dip at the anterior end are to prevent undue pressure on the overlying urethra.

Laparotomy for the correction of displaced uterus is an elective and not an emergent procedure, and it should not be advised unless the hazards involved are minimal, all palliative measures have been exhausted and subse-

quent pelvic comfort can be anticipated. An operation which fails to afford symptomatic relief is a failure, irrespective of the anatomic result.

In a series of 3,400 consecutive office patients, a retrodisplacement was found 429 times, an incidence of about 12.5 per cent. Of these, forty-two patients failed to return for treatment and have been disregarded in this analysis; seventy-two of the remainder had congenital and 315 acquired retroversions or flexions.

TABLE 2.—*Retrodisplacements of the Uterus in a Series of 3,400 Consecutive Office Patients**

Primary corrective operation or operation after palliative measures failed.....	..	87	22
Hysterectomy for tumors (displacement of secondary importance)	27	7
	72	315	
Total.....	387		100

* Exclusive of forty-two who failed to subject themselves to treatment.

Treatment of the malposition itself was unnecessary in forty-seven cases. In the other 268, palliative measures sufficed to relieve symptoms in fifty; bimanual reposition and a pessary effected a cure in seventy-six; twenty-eight patients with "uncomplicated" displacements were operated on after wearing a pessary temporarily, and eighty-seven had a primary operation or were operated on after palliative measures failed to afford symptomatic relief. Hysterectomy for tumor was performed in twenty-seven cases, the uterine dislocation being of secondary importance (table 2).

In reviewing this series of cases, certain significant facts became apparent:

1. Several operations by other surgeons for the cure of developmental defects were followed by recurrence.
2. Many patients with congenital displacements were pregnant when first seen or became so after the application of negative galvanism to the uterus and the treatment of endocrine derangements. Endowment with a congenital malposition does not condemn a patient to sterility.
3. After delivery the uterus may involute in normal position, even though previously congenitally retrodisplaced.
4. Symptomless acquired retroversions were discovered in patients presenting themselves with conditions such as Bartholin cyst, pruritus vulvae, trichomonas infections, cervical polyp, sterility, urinary complaints, colitis and breast tumor. They were more common in postmenopausal women.
5. Successful palliative treatment embraced careful preliminary differential diagnosis as well as the correct therapy for hormonal imbalance, endocervicitis, parametritis and adnexal disease. In some instances a pessary was used after a fixed uterus became mobilized.
6. A high percentage of patients fitted with a pessary were impregnated while wearing the appliance or soon thereafter.

The multiplicity of operations devised for the surgical replacement of a retroverted or retroflexed uterus is not testimony of the uselessness of all of them, as has occasionally been intimated, but is rather evidence of appreciation on the part of discriminating gynecologists that no single technical procedure is universally applicable. Failures seldom represent lack of skill in execution; they more often result from inadequate preoperative differential diagnosis, on the one hand, and overenthusiasm in favor of a particular operation on the other. In a series of 2,550 personal consecutive pelvic operations, including ward service cases, I found that I had utilized some type of intraperitoneal uterine suspension in 286 (table 3).

In several instances the suspension was reinforced with a plication of the uterosacral ligaments, and all laparotomies were supplemented with whatever vaginal plastic repair was indicated.

The relatively small number of Baldy-Webster suspensions is an index of conservatism in operating for a replaceable retrodisplacement, since I am prejudiced in its favor wherever it can be judiciously selected. It can be done quickly, preserves normal uterine mobility, elevates prolapsed ovaries and in my experience has interfered less with subsequent pregnancy and parturition than any other corrective procedure. It is ideal for the patient who has worn a pessary with relief of symptoms, thus demonstrating to both patient and physician that the annoyances have been due to the uterine dislocation and nothing else and that maintaining the uterus in its normal position will effect a cure. Unfortunately its merits have often been responsible for its misapplication. It has been done when no operation was imperative, when the round ligaments were markedly attenuated or when adnexal disease required salpingo-oophorectomy. The intact utero-ovarian ligament, tube and ovary are the only sturdy structures capable of exerting counterpressure against the pull of the transplanted round ligament on the thin leaves of the broad ligament. It is apparent that if the utero-ovarian ligament is cut, as it must be when salpingo-oophorectomy is done, the broad ligament will soon yield to tension and recurrence is inevitable. Other causes of failure are using it for the support of a heavy

TABLE 3.—*Surgical Procedures for Retrodisplacement of the Uterus in 2,550 Consecutive Pelvic Operations**

* Exclusive of operations for displacements associated with tumors.

subinvolted corpus without plicating the uterosacral ligaments at the same time, and suturing the round ligaments too low on the posterior surface of the corpus, so that they serve as a fulcrum instead of as a support.

The large number of cases in which Crossen's modification of the Gilliam operation was done indicates the high incidence of concomitant adnexal disease in the patients subjected to surgical intervention for retrodisplacements. This operation also causes little trouble in event of subsequent gestation and delivery. Some

patients complain of soreness in the region of the round ligament attachment during the early months of pregnancy, but this is transitory and of little consequence. In only one of my cases has the operation been responsible for dystocia during labor, and intestinal obstruction has not followed in any case, so far as I know. The Crossen-Gilliam operation is not contraindicated by salpingo-oophorectomy, but the postoperative antero-posterior excursion of the corpus is somewhat limited as the bladder and rectum empty and fill.

A ventrifixation of the uterus was performed twenty-eight times in women past the menopause when the round ligaments were so short and thick that they could not be conveniently plicated, when the rapid removal of adnexal masses after extensive vaginal work was so easy that hysterectomy did not seem warranted, or when advantageously combined with a Crossen-Gilliam suspension in cases in which the uterus was prolapsed to the first degree. This group includes a few ventrosuspensions, attempted before I learned that the intended suspension usually terminates in a fixation, or the artificially created false ligament so stretches that the displacement eventually recurs.

Mann's plication of the round ligaments is indicated when the uterus is small and not to be sacrificed, both tubes have been removed at a previous operation and the round ligaments are unusually long but not much thinned out. Under these conditions it has proved entirely satisfactory.

Olshausen's suspension tends to immobilize the uterine fundus and thus interfere with proper bladder expansion. It has many strong advocates, but I have utilized it only five times, when speed was important after other prolonged operative procedures.

Coffey's plication of the round and broad ligaments is especially useful when the tubes have been extirpated at a previous operation and the round ligaments are so attenuated that they are almost lost in the reduplicated folds of the broad ligaments, but such cases are rarely seen.

SUMMARY AND CONCLUSIONS

Retrodisplacements of the uterus per se do not cause symptoms.

It is important to ascertain whether a malposition is congenital or acquired, whether the uterus is replaceable or immobilized and whether there is coexisting pelvic pathologic change.

The concealed complication in cases of replaceable displacement causing symptoms is passive congestion.

The true cause of many symptoms credited to a retrodisplacement will be found elsewhere. Careful differential diagnosis is of paramount importance.

A retrodisplacement may be treated prophylactically, expectantly, palliatively or surgically.

Pessaries are used to maintain normal uterine poise and position, not to correct a displacement. When fitted accurately they are worn with perfect comfort.

In a series of 3,400 consecutive office patients, a retrodisplacement was found 429 times, an incidence of 12.5 per cent; 142 of these were subjected to operation.

In a series of 2,550 consecutive personal operations, some form of intraperitoneal uterine suspension was done 286 times.

No single surgical procedure is universally applicable. An operation which fails to afford symptomatic relief is a failure.

580 Park Avenue.

ABSTRACT OF DISCUSSION

DR. BERTHA VAN HOOSSEN, Chicago: Dr. Dannreuther's treatment with pessaries I endorse. He makes the statement that congenital retroversions of the uterus are symptomless and therefore we shouldn't think of treating a symptomless condition. I should like to ask Dr. Dannreuther what he considers the cause of a congenital retroversion of the uterus. It seems to me that if the undescended testicle deserves assiduous treatment we might put a little less assiduous but some more treatment on the symptomless congenital retroversion. I didn't gather whether Dr. Dannreuther made an age limit to the surgical treatment for retroversion. I make a deadline. If a patient is over 40 I feel that she must have had the retroversion for a long time and there is apt to be accompanying fibrosis or seedling fibroids, and as the uterus is an organ that is not very necessary after 40 I invariably do a simple supravaginal hysterectomy. I was disappointed that Dr. Dannreuther never mentioned the Alexander operation, which is the pioneer. The Alexander operation has the advantage that it uses the attenuated distal portion of the round ligament by which to suspend the uterus, and I draw that round ligament up so tight that it really suspends the uterus. I wish the ligaments that support the uterus, the cardinal ligaments and the uterosacral, to have absolutely nothing dragging on them so that they will recover their tone at the end of from three to six months. Of course, during this three to six months the uterus is pulling on those adhesions that have been formed around the round ligaments, and they gradually give way and at the end of six months the uterus will be in a normal condition with all its mobility. I feel that mobility is the first requisite, the thing that we should try hardest to get, and that position of the uterus is secondary.

DR. R. S. CRON, Milwaukee: Dr. Dannreuther has handled the problem of retrodisplacements in a masterful fashion. Two points that he has mentioned should be emphasized. The first is that the postpartum examinations, especially when retrodisplacement is suspected, should be done at the end of the third or the fourth week and again repeated at the sixth or the eighth week. A tipped uterus, even if congenital, corrected at this time and held in place with a properly fitting support, may be permanently corrected. Second, the pessary should be used more frequently, especially for a therapeutic test in uncomplicated retroversion. There are two statements with which I wish to take issue. The first is the routine packing for forty-eight hours of all postabortion uteri with iodoform gauze. A few years ago I reviewed more than 1,000 cases of abortion treated in various ways and found that those treated most conservatively and with the least trauma experienced the most satisfactory convalescence. Consequently, I rarely pack. A retroversion suspected or found at this time is immediately corrected with a pessary. Second, the choice of operation. A brief study of the last 185 operations performed for retrodisplacement of the uterus also showed a multiplicity of operations having been used. It was found necessary or deemed advisable to perform a hysterectomy in slightly less than one fourth of them. The Baldy-Webster technic was used nine times. In spite of the fact that this is the operation advocated by many of America's most prominent gynecologists, I am prejudiced against it. I know of at least six patients who have developed intestinal obstruction following the operation. In the hands of the average operator, at least four different openings may be left into which a loop of intestine may become strangulated. Recurrences, especially retrocession, are not uncommon. A technic described many years ago by Reuben Peterson and similar to the Mayo operation has in my hands proved to be most satisfactory. Each round ligament is drawn through the inguinal ring and anchored to the posterior surface of the anterior sheath of the rectus muscle. This operation was used 120 times, or in about 70 per cent of the cases. In thirty-eight instances it was combined with the approximation of the sacro-uterine ligaments. There was one recurrence, but no other serious complications were encountered. Finally, it has been noted that Dr. Dannreuther has made no mention of the relation of endometriosis to chronic retroversion. I should like to know whether he considers the possibility of regurgitation of the menstrual endometrium through the tubes in congenital or acquired retrodisplacement an indication for its correction.

DR. LOUIS E. PHANEUF, Boston: I appreciate Dr. Dannreuther's lucid presentation of this important subject of retroversions of the uterus. I subscribe to the fact that a retroversion or a retrodisplacement per se seldom causes symptoms but that it is the concomitant pathologic condition which is responsible for the symptoms. Obviously a congenital displacement without symptoms requires no treatment. The frequent association of hypoplasia, dysmenorrhea and sterility with that type of uterus, however, needs our attention. I have found the atrophied uterus after the menopause in retroversion so frequently that in my mind the retroposed atrophic uterus is a fairly normal condition. One of the greatest uses of the pessary which I have found has been in the puerperal uterus which has remained large, with lax ligaments, which can be replaced manually very simply, and which a pessary will hold in position. The wearing of a pessary for a period of six months will frequently allow the ligaments to take up their tonus and thereby correct the position. The wearing of a pessary in a replaceable uterus to determine whether or not the symptoms are caused by the retroversion in my mind is an excellent procedure. In connection with suspension operations, there are three factors which govern the proper surgical replacement of the retroposed uterus, as I see it. The first is to bring the cervix back at right angles to the vagina, the second to bring the uterus forward, and the third to obliterate the space on the sides in order to avoid, so far as it is possible to do so, intestinal obstruction. This is accomplished by shortening the uterosacral ligaments by doing a round ligament suspension in such a way that the space on the sides is obliterated. It is my custom to do some sort of suspension after having operated for adnexal abnormality, with the end in view of preventing the formation of an adherent retroversion.

DR. O. S. KREBS, St. Louis: I merely want to mention a phase of prophylaxis of retrodisplacement of the uterus. It seems that at the end of the second week after delivery the rule is for the uterus to be forward, that the displacement occurs between that time and the fourth week, when from 20 to 41 per cent are found displaced posteriorly. Williams says one out of four or five, and Lynch 41 per cent. In October 1937 I began introducing a collapsible pessary, the Finley pessary of the Smith-Hodge type, in treating all private obstetric patients delivered by Dr. Royston and myself, just before they left the hospital. It has also been the custom for these patients to omit taking any douches for two weeks after getting home, and to insert into the vagina every other night a large capsule filled with 80 per cent beta lactose and 20 per cent boric acid, as suggested by Roblee. In the small series under consideration the results are not entirely tabulated, but the frequency of retrodisplacement after the puerperium is over is 18 per cent in primiparas and multiparas combined. There is a high frequency of congenital displacements in our cases, about 16 per cent in the aforementioned group, which were considered in the results, however, and it is noteworthy that among all the primiparas only those that we felt had congenital displacements ended with retrodisplacements at the end of the puerperium. Four of the patients with congenital displacements during early pregnancy had anteverted uteri when discharged from our care. Not considering the lessened incidence of displacement following delivery with the foregoing regimen, which may be worth while, the improved involution in practically all cases regardless of the final position of the uterus was very striking. No douches were given during this postpartal period, so the effect of heat can be dismissed. Probably the greatest factor in subinvolution is a local one and that is an abnormality of circulation which accompanies the displacement, and the results are obtained by the uterus being maintained in its normal position when involution is active. In addition to better involution, the cervix recovered from the effects of labor at an earlier time and more completely. Since this series of cases has been under observation it has not been found necessary to cauterize the puerperal cervix for erosion or endotrachelitis alone.

DR. A. C. HIRSHFIELD, Oklahoma City: Dr. Dannreuther has rightly emphasized the lack of symptoms in the uncomplicated case and has reemphasized the fact that surgery is ordinarily not indicated in these cases, but men practicing in

large hospitals and medical centers would be surprised if they realized the percentage of routine surgery, in the hospitals in the hinterlands, which consists of operations on tubes and retrodisplacements. Since I recognized the fact that surgery is not indicated in the ordinary case of salpingitis and retrodisplacement, I have not appeared in the operating room as often as I used to, and I have no enthusiasm for surgical intervention in these cases. To get back to the legal aspect of this matter, I wonder whether physicians realize how many large damage suit judgments are obtained because women who have been in minor accidents, particularly in taxicabs, show up afterward with retrodisplacement. In Oklahoma City the taxicabs compete with the street cars, and one can ride any reasonable distance for 10 or 15 cents. There are many taxicab accidents, and for years the damage suit lawyers managed to find physicians who found retrodisplacements in these women and who qualified as experts and testified more or less convincingly to the juries that these retrodisplacements were caused by taxicab accidents. The taxicab attorneys employed one or two of us who had a more or less scientific view to combat this wave of damage suit cases in favor of the retroverted uterus. By means of charts and models and impromptu lectures we went before these juries and demonstrated that these conditions were either congenital or caused by childbirth or other more or less natural feminine causes and were not caused by ordinary taxicab accidents.

DR. W. H. VOGT, St. Louis: I was glad to see that Dr. Dannreuther is still so old fashioned as to use the pessary. There is a definite place for the pessary when used properly with the proper indications and the proper type of pessary. There are contraindications to the use of the pessary that everybody must recognize, and Dr. Dannreuther, I think, has brought out some of those. In inflammatory conditions of the pelvis they should not be used; if the uterus cannot be elevated the pessary should not be used, because it will do more harm than good. I am not one of those who believe that the retroversion or retrodisplacement of the uterus which gives no symptoms should not be treated. There are certain types of retrodisplacement, that type of congenital retrodisplacement with a general atrophy of the pelvic organs and general ill development of the body, that do not need any treatment; treatment there is directed in a general way and not locally. Likewise, those cases of retrodisplacement which occur in the menopause I don't believe need any treatment. In the atrophic uterus of the menopause no treatment is needed, but in all other cases of retrodisplacement, even though there are no symptoms, I think treatment is indicated, because I feel convinced that the uterus acts as a wedge and that the retrodisplacement is simply a forerunner of a future prolapsus.

DR. WALTER T. DANNREUTHER, New York: In reply to Dr. Van Hoosen's inquiry regarding my opinion concerning the embryologic factors responsible for a congenital defect, I confess that I don't know how they operate. Even if we did know, it seems unlikely that such knowledge would be of practical value. To institute any effective therapeutic measures it would be necessary to make an exact diagnosis, which would involve the routine examination of all female infants and children. The Alexander-Adams operation of course was popular forty years ago, but modern abdominal surgery no longer carries with it the hazards of forty years ago. One does not hesitate to open the peritoneal cavity today, whereas forty years ago there were frequent consultations before such a serious step was undertaken. The Alexander-Adams operation requires two incisions instead of one, affords no opportunity to make an intraperitoneal exploration, is sometimes attended by technical difficulties when the round ligaments are thin and hard to find in the inguinal canal, and eventuates in a certain percentage of unsatisfactory results. Dr. Cron called attention to a typographic error in my paper which escaped my notice, namely, the recommendation that the uterus be packed after abortion; the qualifying word "therapeutic" should have been included. No instances of intestinal obstruction following Baldy-Webster operations have come to my attention, although my patients, both clinic and private, have an excellent follow-up. On the other hand it is evident that, if sutures are not placed properly in doing this operation, intestinal

obstruction might easily occur. I prefer Pagenstecher linen to catgut for stitching the round ligaments to the uterine corpus. No reference was made to endometriosis because it does not seem justifiable to put the tag of retrodisplacement on such a condition. All the anatomic relationships may be so distorted by endometriosis, just as they are in cases of pelvic tuberculosis, that I think that such cases were properly omitted from my statistical data. Under these circumstances a retrodisplacement is entirely secondary to another primary and more important pathologic process. The medicolegal aspects of uterine displacements are interesting, but the limitations of this paper precluded a reference to them.

TREATMENT OF PNEUMOCOCCIC MENINGITIS WITH SULFAPYRIDINE

AND THE SODIUM SALT OF SULFAPYRIDINE

HORACE L. HODES, M.D.
HARRY S. GIMBEL, M.D.

AND
GEORGE W. BURNETT, M.D.
BALTIMORE

Since the demonstration by Whitby¹ of the effectiveness of sulfapyridine against pneumococcal infections in mice, many clinical reports have shown that the drug is of definite value in the treatment of pneumonia in man. It appears that the mortality rate from pneumonia in both children and adults is reduced when sulfapyridine is used.² Reports have appeared which indicate that the drug may be of value also in pneumococcal meningitis.³ However, the number of cases thus far described is so small that one cannot be certain that the prognosis in this disease will be, in general, altered by the use of sulfapyridine. There are published in the literature the records of only fourteen

From Sydenham Hospital, Baltimore City Health Department. The sulfapyridine and its sodium salt were furnished by Merck & Co., Inc., Rahway, N. J., under the names "Dagenan" and "Dagenan Sodium." Dr. E. K. Marshall, Jr. gave valuable advice on the dosage and method of administration of the sodium salt of sulfapyridine and supplied us with the first samples of the drug. Dr. Perrin H. Long showed constant interest in the progress of this study and made many helpful suggestions.

patients with pneumococcal meningitis who were treated with sulfapyridine alone. Eight of the fourteen recovered.

The present communication deals with the use of sulfapyridine and its sodium salt⁴ in the treatment of seventeen patients with pneumococcal meningitis admitted to the Sydenham Hospital between October 1938 and May 1939. Eight of these seventeen (47 per cent) recovered completely. Antipneumococcal serum was not employed in treating any of these patients. While it is difficult to attempt to estimate the value of any form of therapy in so small a series of patients, it should be pointed out that when no specific therapy is used the mortality rate in pneumococcal meningitis is so nearly 100 per cent that the survival of eight or seventeen patients seems striking enough to warrant detailed consideration.

This experience with sulfapyridine is in sharp contrast with our results obtained in treating pneumococcal meningitis during the eight years previous to the introduction of this drug. Between 1930 and 1936 no specific therapy was employed, and all of the twenty-nine patients treated during this time died. From December 1936 to October 1938, seventeen patients were treated with sulfanilamide but only one recovered. In all, forty-six patients were treated between January 1930 and October 1938 with only one recovery.

Four of the seventeen patients treated with sulfapyridine or its sodium salt were infants under 1 year of age. Five patients were between the ages of 6 and 12 years, while eight were adults varying in age from 28 to 54 years. Six were white and eleven were Negroes.

Pneumococci were cultured from the spinal fluid in each case. In every case these pneumococci were identified by cultural characteristics, by mouse inoculation and by the Neufeld-Sabin reaction with type-specific serum. The following types were isolated: I, III (twice), V, VI (twice), IX, XII (twice), XIV, XIX, XXII, XXIII, XXV, XXVII, XXIX and XXXI.

With the exception of the four patients who die within twenty-four hours after admission, the finding of pneumococci was confirmed by one or more additional spinal fluid cultures. From the blood of nine patients, pneumococci of the same type as that found in the spinal fluid were isolated.

The meningitis was of otitic origin in eight cases. In three instances the meningitis developed during the course of pneumonia and in one case it followed an infection of the eye. No source of the infection could be discovered in the remaining five cases.

METHOD OF ADMINISTRATION OF SULFAPYRIDINE AND SODIUM SULFAPYRIDINE

The first six patients were given sulfapyridine by mouth, while the remaining eleven received in addition the sodium salt of sulfapyridine intravenously. The amount of drug given by mouth varied between 1 and 12 Gm. in twenty-four hours, depending on the patient's age, on his condition and on the concentration of the drug in the blood and spinal fluid. In very young infants from 1 to 3 Gm. daily was given as compared with from 6 to 12 Gm. in older children and adults. In each case the total twenty-four hour dose was given immediately when the diagnosis of pneumococcal meningitis was made; one fourth of this amount was then

4. Marshall, E. K., Jr.; Bratton, A. C., and Litchfield, J. T., Jr.: The Toxicity and Absorption of 2-Sulfanilamidopyridine and Its Sodium Salt, *Science* 88: 597 (Dec. 23) 1938.

given every six hours. The full dose of sulfapyridine was continued by mouth until the patient seemed entirely well clinically and until several successive cultures of spinal fluid were sterile; the dose was never reduced before the temperature had been normal for one week. After this time the dosage was halved for several days and then the drug was discontinued entirely. On one occasion it was resumed because the occurrence of a relapse was suspected.

On admission many of the patients in this series were comatose or delirious and required the administration of the drug by nasal tube. This was continued until the patient was able to swallow.

In the treatment of the last eleven patients in this series the sodium salt of sulfapyridine was employed in addition to the oral administration of sulfapyridine. As Marshall⁴ has shown, the sodium salt, unlike sulfapyridine itself, is freely soluble. It is most conveniently used in distilled water in a 5 per cent solution, which is approximately isotonic. It should be emphasized that such a solution is extremely alkaline (p_H almost 11) and cannot be given intrathecally or subcutaneously but only intravenously.⁵ The sodium salt proved to be of great value. When it first became available it was given only to those patients who were unconscious or comatose and unable to swallow sulfapyridine. Later we employed it also in treating those patients in whom the concentration of the sulfapyridine in the blood and spinal fluid remained low during the oral administration of the drug. In such cases one or two daily intravenous injections of the sodium salt served to bring the concentration of sulfapyridine in the blood and spinal fluid to high levels. The intravenous administration of the sodium sulfapyridine proved to be of great value also for those patients who persistently vomited sulfapyridine given by mouth. At the present time we believe that the oral administration of sulfapyridine should be combined with a regular course of the sodium salt given intravenously. The plan of treatment which we now recommend and which we have employed in treating the last four patients, all of whom recovered, is as follows:

The oral administration of the drug is instituted on admission and continued in the manner already described. In addition, intravenous therapy with a 5 per cent solution of sodium sulfapyridine in distilled water is begun. An initial dose of 0.1 Gm. per kilogram of body weight is injected. Following this, 0.03 Gm. of the sodium salt per kilogram of body weight is given intravenously every six hours until the patient shows definite clinical signs of improvement and until two successive lumbar punctures are sterile. After this, the sodium sulfapyridine is given only twice a day for several days longer, and then it is discontinued. Intravenous therapy should be resumed at the first indication that a relapse has occurred.

None of the patients treated with sulfapyridine received antipneumococcus serum. Forced spinal drainage was not employed and lumbar punctures were done only for diagnostic purposes and occasionally to relieve pressure symptoms. Supportive measures, such as the administration of intravenous fluids and frequent blood transfusions, were given as necessary. Myringotomy was performed in six cases but it was thought advisable in only two cases to attempt to eradicate the original focus of infection by extensive surgical methods. A mastoidectomy was performed on one of these

patients (patient 3), who recovered, but it was very doubtful that the operation exerted any definite effect on the course of the meningitis. In the other case the meningitis apparently followed pneumococcic panophthalmitis of one eye. Enucleation was not followed by any improvement in the patient's condition, and he eventually died.

CONCENTRATION OF SULFAPYRIDINE IN BLOOD AND SPINAL FLUID

With a modification of Marshall's⁶ method for sulfanilamide, the concentration of free sulfapyridine in the blood and spinal fluid was determined on a number of occasions in twelve cases. It was found that when the drug was given orally there was great variation in the concentration of sulfapyridine. There was no good correlation between the dose of the drug given by mouth and the level of sulfapyridine in the blood and spinal fluid. The concentration of the drug in the spinal fluid in those patients who received the drug by mouth varied only from 1.1 to 11.4 mg. per hundred cubic centimeters. It was generally higher in those patients who also received sodium sulfapyridine intravenously. In one such case the concentration in the spinal fluid

TABLE 1.—Treatment of Pneumococcic Meningitis at Sydenham Hospital, 1930-1939

Treatment	All Cases			Adequately Treated Cases Excluding 24 Hour Deaths		
	Number Treated	Recovered		Number Treated	Recovered	
		Number	Per Cent		Number	Per Cent

Sulfanilamide.....	17	1	6	12	1	8
Sulfapyridine.....	17	8	47	13	8	61

reached 29 mg. per hundred cubic centimeters. The concentration of sulfapyridine in the blood was usually from 30 to 50 per cent higher than it was in the spinal fluid.

TOXIC EFFECTS OF SULFAPYRIDINE

During the course of treatment with the large doses of sulfapyridine and its sodium salt which were employed, a number of toxic effects of the drug were noted. The drug produced nausea and vomiting in more than half the patients, but these symptoms were severe in only one case. Cyanosis of mild degree was seen in four of the patients; it was accompanied by no untoward effects. The drug did not produce anemia of appreciable degree in any of the cases. In one adult (D. C.) mild leukopenia was noted, and in one child (C. M.) severe granulocytopenia developed. Owing to an oversight, this child continued to receive the drug ten days after it was believed to have been withdrawn. The white blood count dropped to 4,000 cells, of which 96 per cent were lymphocytes. The granulocytopenia was accompanied by fever of 104 F. and by membranous pharyngitis. The drug was discontinued and supportive measures were instituted. The patient improved almost at once and the temperature became normal in six days. The white blood cell count rose gradually until it reached 9,500 with 70 per cent polymorphonuclear leukocytes ten days after the discovery of the granulocytopenia.

In three of the cases the administration of sulfapyridine caused gross hematuria. In the first case (case 2), the hematuria appeared on the fifth day after the institution of sulfapyridine therapy. The hematuria was not accompanied by oliguria, hypertension or an increase in the nonprotein nitrogen of the blood. Within four days after withdrawal of the drug, the urine was normal microscopically; the number of formed elements as measured by the Addis count was within normal limits, and phenolsulfonphthalein tests

pyridine therapy was begun again and was continued for the next four days. During this time gross hematuria reappeared and persisted until two days after the drug was again discontinued.

In a third case (case 17) hematuria developed fourteen hours before death. Autopsy showed very clearly that death was not caused by the hematuria but was due to very extensive meningitis which had apparently not been affected by sulfapyridine. Gross examination showed that the pyramids, calices, pelves and ureters

were normal. Apparently no permanent damage to the kidney resulted from the hematuria.

In the second case (case 9) hematuria developed on the fourth day of treatment with sulfapyridine and its sodium salt. In this case also the hematuria was not accompanied by changes in blood chemistry or by elevation in blood pressure, and there was no oliguria. Fluids were forced but, since the spinal fluid cultures were still positive, the intravenous administration of sodium sulfapyridine was continued. The spinal fluid became sterile two days after the onset of hematuria, and when the sodium sulfapyridine was withdrawn four days later both the urine and the spinal fluid were normal. About two weeks later the patient showed clinical evidence of a relapse, and it was suspected that she was suffering from a brain abscess. Sodium sulfa-

pyridine therapy was begun again and was continued for the next four days. During this time gross hematuria reappeared and persisted until two days after the drug was again discontinued.

In a third case (case 17) hematuria developed fourteen hours before death. Autopsy showed very clearly that death was not caused by the hematuria but was due to very extensive meningitis which had apparently not been affected by sulfapyridine. Gross examination showed that the pyramids, calices, pelves and ureters

of both kidneys, as well as the bladder, contained gravel-like calculi. These calculi were very rough, with many pointed spicules. Dr. A. Calvin Bratton in Dr. E. K. Marshall Jr.'s laboratory showed that these small calculi were made up almost entirely (85 per cent) of the acetyl derivative of sulfapyridine. Microscopic sections showed that the calculi apparently had eroded the epithelial cells lining the pelves, ureters and bladder and had caused hematuria by injury to the underlying capillaries. No crystals of sulfapyridine or calculi were found in the glomeruli or tubules and no evidence of injury to these structures was found.

It appears, therefore, that the hematuria caused by sulfapyridine is due to mechanical injury to the urinary tract. It seems reasonable to suppose that the hematuria

turia will not be accompanied by serious or permanent interference with renal function, unless the precipitation of the acetyl sulfapyridine is so extensive as to produce blockage of the tubules or urters.

Dr. E. K. Marshall Jr.⁷ offers the following explanation for the formation of calculi of acetyl sulfapyridine in the urinary tract: When sulfapyridine is ingested, part of it is acetylated and is excreted in the urine with some free sulfapyridine. The amount of sulfapyridine which is acetylated varies greatly with the individual patient. Acetyl sulfapyridine, which is not very soluble at best, is even less so in acid mediums. It is probable that even when the concentration of this substance is high in the blood it remains in solution in the glomerular filtrate. However, as the urine becomes more concentrated and more acid as it passes down the tubular system, precipitation of the crystalline acetyl sulfapyridine may occur. These sharp-edged crystals and small calculi formed around them probably cause hematuria by mechanical injury. Dr. Marshall suggests that with a given dose of sulfapyridine the danger of the occurrence of hematuria might be lessened by the administration of alkali and by supplying an adequate fluid intake.

RESULTS FOLLOWING TREATMENT

Table 2 summarizes our experience with the use of sulfapyridine and its sodium salt in pneumococcic meningitis. As already stated, eight of the seventeen patients treated (47 per cent) recovered. Up to the present time no sequelae of any kind have been noted and these patients appear to be entirely well. This result is particularly striking when the condition of the patients on admission to the hospital is considered. Four were moribund and died in less than twenty-four hours; ten were critically ill and delirious or comatose, while three were only moderately ill. Of the thirteen patients who survived more than twenty-four hours, only five failed to recover. Among the seventeen patients there were four under 12 months of age; all these infants died in less than twenty-four hours after the beginning of treatment with sulfapyridine. Three of the five children between the ages of 6 and 12 years recovered, as did five of the eight adults in the group.

In those patients who recovered, clinical improvement was noted very soon after treatment with sulfapyridine was begun. Usually the first evidence of beneficial action of the drug was improvement in the patient's mental status. On a number of occasions the patient who had been stuporous or irrational became oriented and alert within twenty-four hours after the beginning of treatment. Among the patients who recovered, the temperature reached normal within four days and the spinal fluid cultures became sterile within five days, with the exception of one (patient 1), whose spinal fluid cultures showed pneumococci for seventeen days. In two cases (5 and 7) a relapse occurred with the transient appearance of pneumococci in the spinal fluid. A very dramatic example of the prompt effect of the drug is shown in the accompanying chart.

Pneumococci were recovered from the blood cultures on admission of four of the patients who recovered.

The blood cultures in these cases became sterile within a few days after the beginning of treatment.

Three of the patients who recovered showed paralysis of the facial nerve of the peripheral type during the course of their illness. During convalescence, however, the paralysis gradually became less marked and all three patients eventually regained complete use of their facial muscles.

In one instance death was caused by a cerebellar abscess. At autopsy the meninges were found to be perfectly normal. Apparently treatment with the sulfapyridine had brought about complete resolution of the infiltration and infection in the meninges but had not caused healing of the brain abscess.

COMMENT

It seems evident that the mortality rate from pneumococcic meningitis can be reduced by the use of sulfapyridine and its sodium salt. The outlook for the average patient with this disease has been improved,

Course of meningitis due to type V pneumococci in a Negro girl aged 11 years (case 3). Dramatic and rapid improvement after sulfapyridine therapy was started.

perhaps by 50 per cent. Our experience indicates that the drug is effective against all types of pneumococci.

One of the great handicaps encountered in treating meningitis with sulfapyridine is the irregularity of the absorption of the drug, which probably accounts for the great variation in its concentration in the blood and spinal fluid. This drawback may be eliminated by the use of the sodium salt of sulfapyridine. By administering the sodium salt at regular intervals, as we have done in treating our last four patients, all of whom recovered, the concentration of sulfapyridine in the spinal fluid may be maintained at any desired level. We believe that this is the important function of the sodium salt, which should be used in amounts sufficient to maintain the spinal fluid concentration of sulfapyridine between 10 and 15 mg. per hundred cubic centimeters.

That the use of sulfapyridine may be accompanied by serious toxic effects is, of course, well known. However, in dealing with meningitis, the most dangerous of all pneumococcic infections, it may be necessary to continue treatment with the drug despite these untoward effects. For example, we believe that the drug should be given even in the face of hematuria, since the patient's life depends on the action of the drug.

There remains the possibility that better results might be obtained by combining sulfapyridine with antipneumococcus serum. On this point we have no data to offer.

REPORT OF CASES⁸

CASE 2.—A. P., a white boy aged 7 years, was admitted to the hospital Jan. 16, 1939, and discharged well February 4.

Five days before admission, the child complained of pain in the right ear. The next day he became drowsy and remained so until admission to the hospital. On the night before entry he became "dizzy" and complained of a great deal of pain in the back of his neck when he attempted to raise his head.

On arrival at the hospital the patient, who was well developed and well nourished, did not appear to be critically ill. His neck was slightly stiff and Kernig's sign was present. On otoscopic examination the left drum was seen to be bulging, but no mastoid tenderness or edema was present. Physical examination otherwise was entirely negative.

On admission the spinal fluid showed 2,000 cells per cubic millimeter but no organisms were seen on smear. Sulfanilamide therapy was begun at once. Myringotomy of the left ear drum was done with the release of a large amount of thick pus. The next day, type I pneumococci were recovered from cultures of the spinal fluid and of the pus from the ear and from the throat, and sulfapyridine therapy was begun. Six Gm. a day was given for four days. On the fourth day of sulfapyridine treatment, hematuria developed with passage of a few blood clots. Sulfapyridine was immediately discontinued and within the next five days the urine became clear and negative microscopically. All kidney function tests were normal one week after the hematuria had appeared.

The spinal fluid cultures were negative at the time the sulfapyridine was discontinued, and the patient did not require any further medication.

The temperature on admission was 103 F. and returned to normal on the second day. On the fourth day the temperature rose to 102 F. At this time the left ear drum was reopened and pus was obtained, following which the temperature returned to normal.

On admission the patient was found to be strongly sensitive to a test dose of rabbit and horse serum, and consequently antipneumococcus serum could not be used.

On discharge the left ear was completely healed. The urine was normal and no residual changes were present.

LABORATORY DATA

Spinal fluid cultures were positive for pneumococci (type I) January 16 and 17 but sterile thereafter.

Culture of pus taken from the left ear was positive for pneumococci (type I) January 16.

Culture of material taken from the throat was positive for pneumococci (type I) January 17.

The urine was normal, except for gross hematuria on the fourth day in the hospital, which cleared in five days and remained normal thereafter. The Addis count was normal.

Nonprotein nitrogen was 40.2 mg. per hundred cubic centimeters of serum at the time of hematuria.

Blood culture was sterile January 17.

CASE 3.—C. M., a Negro girl aged 11 years, was admitted to the hospital Feb. 11, 1939, and discharged well March 24.

Six days before admission the patient noticed a copious discharge from her left ear. The next day her gait became unsteady. She continued to have fever and became increasingly weak until on the day of admission to the hospital she suddenly became unconscious.

Physical examination on admission showed that she was well developed and well nourished; she appeared critically ill. She was irrational and failed to respond to stimuli. She was in opisthotonos. There was an internal squint of the left eye. Foul pus drained from the left ear and there was a watery nasal discharge. The Kernig and Brudzinski signs were present. Lumbar puncture revealed cloudy spinal fluid which

contained 4,300 cells, nearly all of which were polymorphonuclear leukocytes. On smear there were present numerous gram-positive diplococci which proved on culture to be type V pneumococci. The patient was treated with sulfanilamide for two days without improvement, and a simple left mastoidectomy done twenty-four hours after admission was not followed by any change in her condition. At the end of the patient's second day in the hospital the temperature was 105.6 F. She was in a comatose condition and appeared to be moribund. At this point she was given 70 cc. of a 5 per cent solution (3.8 Gm.) of the sodium salt of sulfapyridine intravenously and oral administration of sulfapyridine (6 Gm. a day) was begun. During the next twenty-four hours the temperature dropped to normal; the patient became conscious and was able to speak rationally. She received 6 Gm. of the drug each day for fifteen days and then 4 Gm. a day for the next seven days, after which time the sulfapyridine was discontinued. In addition to the sulfapyridine by mouth, she was given daily injections of the sodium salt of sulfapyridine intravenously for five days.

As noted, the temperature fell from 105.6 F. to normal within twenty-four hours after the first intravenous injection of sodium sulfapyridine. Thereafter it did not rise above 100.6 F. (rectal) until on the twenty-eighth day in the hospital, when it rose to 103 F. owing to the onset of agranulocytic angina. Ten days later the temperature became normal and remained so until discharge.

The mastoid wound healed uneventfully and at the time of discharge only a small granulating area still persisted. The spinal fluid count decreased from 4,300 cells on admission to 13 cells eight days later. The spinal fluid became sterile within twenty-four hours after the beginning of sulfapyridine therapy and remained so thereafter.

The chart is a graphic illustration of the patient's course during the first nine days in the hospital.

LABORATORY DATA

The spinal fluid cultures were positive for pneumococci (type V) February 11 and 13, and sterile February 14, 19 and 23.

The blood cultures were sterile February 11 and 15.

Blood counts showed: February 11, hemoglobin content 14 Gm., white blood cells 14,000 with 88 per cent polymorphonuclears; March 10, white blood cells 4,100 with 2 per cent polymorphonuclears and 98 per cent mononuclears; March 20, white blood cells 9,500 with 70 per cent polymorphonuclears.

Cultures of material taken from the ear and from the mastoid were positive for pneumococci (type V).

Examination of the urine showed 5 or 6 white blood cells per high power field, 2 plus albumin and a trace of acetone. Subsequent examinations were negative.

Culture of material taken from the throat at the time membrane appeared in the throat showed many beta hemolytic streptococci, group A, Lancefield.

SUMMARY

1. Seventeen patients with pneumococcic meningitis were treated with sulfapyridine or with sulfapyridine and its sodium salt.

2. Eight of these seventeen patients (47 per cent) recovered completely. Four of the nine who failed to survive died in less than twenty-four hours after admission to the hospital.

3. Sulfapyridine given by mouth is absorbed irregularly and only in limited amounts. It is recommended that the use of this drug be supplemented by the intravenous administration of sodium sulfapyridine at regular intervals. The concentration of free sulfapyridine in the spinal fluid should be maintained at a level of from 10 to 15 mg. per hundred cubic centimeters.

4. Certain toxic symptoms caused by sulfapyridine have been encountered. These include granulocytopenia and hematuria, neither of which was fatal in any of our cases.

8. Owing to lack of space reports of only case 2 and case 3 are included in THE JOURNAL. Reports of all seventeen cases will be found in the authors' reprints.

5. Hematuria occurring during treatment with sulfapyridine has been shown to be due to the formation of small calculi made up chiefly of the acetyl derivative of sulfapyridine. These calculi apparently produce hematuria by injury to the pelves, ureters and bladder.

6. It appears that the prognosis in pneumococcic meningitis may be greatly improved by the use of sulfapyridine and its sodium salt.

A HITHERTO UNDESCRIBED SURGICAL PROCEDURE RELIEVING ATTACKS OF ANGINA PECTORIS

ANATOMIC AND PHYSIOLOGIC BASIS

RUPERT B. RANEY, M.D.

LOS ANGELES

Despite the various approaches to the problem of angina pectoris, uniformly complete relief from the condition by surgery or medicine has not been heretofore attained. On the assumption that coronary spasm occurs during attacks and is responsible for anginal pain, another operation has been designed which, so far as my experience permits of statements, seems to give uniform relief not by anesthesia but by prevention of coronary spasm.

It seems to be fairly generally accepted that coronary spasm occurs during seizures, but the mechanism is a much disputed question, confusion arising primarily from the reasonably well established normal behavior of these vessels. Any discussion on the surgical treatment is hardly complete without mentioning the name of Sir James Mackenzie,¹ whose timely criticism marks the dividing line between faulty speculation and sound scientific reasoning.² He suggested that a reinvestigation of the entire subject was necessary before any conclusions whatever could be drawn.

PHYSIOLOGIC BASIS FOR OPERATION

Following the suggestion of Mackenzie, Anrep and Segall³ reported from their results in animal experimentation that sympathetic impulses under normal physiologic conditions induced coronary dilatation, a finding which would be expected from the known emergency function of the sympathetico-adrenal mechanism.⁴ The work of Anrep and Segall was later verified by Kountz, Pearson and Koenig⁵ by experiments conducted on human heart-lung preparations. They further observed that when the normal physiologic conditions in the coronary system were altered, for example, arteriosclerosis and change in hydrogen ion concentration of the perfusion fluid, the action was variable, often reversed.

The reversed action following sympathetic stimulation with reference to other organs of the body has been

established by Morat,⁶ Doyon,⁷ Veach,⁸ McCrea and McSwiney⁹ and numerous others. Also it is well known that the action of efferent nerve impulses, whether sympathetic or otherwise, depends on the conditions at the myoneural junction rather than on the character of the impulse. This is best shown by experiments with crossed nerve sutures, of which the most pertinent are those of Langley and Anderson,¹⁰ Cannon, Binger and Fitz,¹¹ Horrax,¹² Ballance¹³ and Duel and Ballance.¹⁴

A survey of the literature forces one to agree with Wiggers¹⁵ that "the nervous control of the coronary circulation and its physiological importance have not been demonstrated as definitely as the uninitiated are led to believe." Furthermore, Anrep¹⁶ has attached considerable significance to pathologic changes in the coronary arteries with reference to altered function. He states (p. 94) that:

The experiments made of fresh human material are far too few to allow us to draw definite conclusions. Still fewer are the experiments made on human hearts which show some pathological changes of the coronary system. Anitchkov and his colleagues have worked on resting human hearts some hours after death. They report that, in cases of arteriosclerosis and diphtheria, adrenalin, even in large doses, ceases to have any effect on the coronary blood vessels. We have had no opportunity of verifying this result; there is no doubt, however, that in arteriosclerotic conditions the coronary blood vessels behave quite differently from normal.

Unfortunately the older clinical impression that sympathetic impulses were coronary constrictor in their action during an attack of angina pectoris was discarded and replaced by the more recent concept of the normal action, the altered or reversed action resulting from pathologic changes not being taken into consideration. White¹⁷ expressed this more recent and fairly general clinical opinion, which is well brought out by the following quotation (p. 235):

Why resection of the superior cervical ganglion alone, as recommended by Coffey and Brown, should relieve a certain number of cases of angina pectoris remains a mystery. No afferent neurons have been found in the upper portion of the cervical sympathetic trunk (cf. chapter III). The only plausible explanation put forward was that a greater portion of the coronary constrictor fibers run through the superior cardiac nerve, and that its interruption increases the irrigation of the myocardium. In view of the more recent physiological findings, however, this can no longer be regarded as a valid explanation.

seizure they respond to these drugs in the same fashion as their observed action on peripheral vessels cannot be logically disposed of.

Furthermore, the interruption of sympathetic efferent pathways is known to have given relief from attacks in a fair percentage of cases. This was shown by Coffey and Brown¹⁹ when they reported their results from resection of the left superior cervical ganglion, and, since the superior cardiac nerve is now known to be

Fig. 3.—The artist's conception of the operation after exposure of the sympathetic chain and rami communicantes.

almost entirely efferent, the contribution accordingly was of exceptional value, because it shows that attacks were occasionally prevented by partially checking the inflow of sympathetic efferent impulses. Certainly the afferent mechanism was not sufficiently altered by the operation to explain the results (fig. 1). This evidence likewise must be taken into account.

Thus, although it appears that the normal and predominant action of sympathetic impulses in coronary physiology is to produce dilatation, the contention arises that under pathologic conditions—for example angina pectoris—the action is reversed; that is, such impulses produce coronary constriction. If this contention is sustained, we then have a single explanation for all the manifestations of the disease; an operation designed to interrupt this discharge of impulses could therefore be reasonably expected to give relief. However, before an operation is designed, the reaction of blood vessels to preganglionic and postganglionic sympathetic denervation must be taken into consideration.

The Meltzers²⁷ and Elliott²⁸ showed that, following postganglionic sympathetic denervation of smooth muscle, a permanent spastic condition developed from the direct action of epinephrine, muscle metabolites and other products normally found in the blood; they further observed that, following preganglionic denervation, spasm did not occur. Thirty years later Smithwick, Freeman and White²⁹ verified these observations on

smooth muscle of blood vessels. They then applied preganglionic denervation in the treatment of Raynaud's disease with remarkable success.

ANATOMIC CONSIDERATIONS

On the assumption, then, that an abnormal action of sympathetic impulses resulting from pathologic changes at the myoneural junction is responsible for an attack of angina pectoris, an operation was planned to interrupt the pathways conveying these impulses. Anatomically it is possible to avoid the production of a Horner's syndrome, and at the same time to remove completely the sympathetic influence on the cardiac mechanism (fig. 2). The anatomy is well described by Ranson,³⁰ Kuntz,³¹ Heinbecker³² and others. To remove completely this influence it would be necessary to operate on both sympathetic trunks; however, unilateral (left) section so far is all that has been required for complete relief from attacks.

CHOICE OF ANESTHESIA

The choice of anesthesia is of considerable importance and should perhaps receive some attention here. All factors likely to increase emotional stress should be eliminated for the purpose of preventing the possibility of a fatal seizure. Leary³³ pointed out that death can occur from prolonged coronary spasm, even without thrombus formation. Adequate sedation should therefore be employed during the hospital interim prior to operation. If avertin with anylene hydrate is administered thirty minutes before the patient is conveyed to the operating room, it will do away with the emotional stress usually associated with this unpleasant trip; of further advantage, its action is vasodilator on the vascular tree. Finally, infiltration of the operative field with procaine hydrochloride gives a satisfactory anesthesia.

Fig. 4.—The artist's sketch here shows the operation completed; the rami communicantes have been sectioned and the sympathetic trunk between the fifth and sixth dorsal ganglia has been sectioned. The proximal end of the trunk has been sutured to the deep muscle layers as an added precaution against regeneration.

TECHNIC OF OPERATION

The operation is done through a paravertebral incision extending from the lower border of the second rib to the upper border of the sixth rib; whether on the left

on the right side, the technic is the same. A short portion of each of the third, fourth and fifth ribs is resected; the intercostal muscles are removed; thus the neurovascular bundles are exposed. The sympathetic chain from the second to the fifth dorsal ganglion and their corresponding rami communicantes are then exposed extrapleurally (fig. 3). Lastly, the operation is completed by section of the rami communicantes from

Fig. 5.—Electrocardiograms taken April 23, before the operation. Note particularly the abnormal inversion of the T wave in lead 1.

the intercostal nerves and section of the sympathetic chain between the fifth and sixth dorsal ganglions (fig. 4).

Exceptional care should be exercised in separating the parietal pleura from the vertebral column, since a sudden mediastinal shift from a spontaneous pneumothorax might prove disastrous. Furthermore, a blind approach into the mediastinal structures will almost certainly lead to uncontrollable technical difficulties. To the surgeon experienced in this field these remarks are no doubt unnecessary, but to the novice they should convey the gravity of the situation at hand.

REPORT OF CASES

Eleven patients have been operated on by the procedure outlined. There have been no deaths, and all have obtained complete relief from what had previously been desperate attacks of angina pectoris. The following cases were selected and are presented in detail because they show the results that can be obtained even in the face of other major complicating disorders.

CASE 1.³⁴—Daily attacks of angina pectoris for three years in a middle aged man. Moderate arteriosclerotic hypertensive heart disease and diabetes mellitus. Partial relief by nitrites during attacks. Electrocardiographic evidence of coronary disease. Complete relief from anginal seizures by preganglionic section of rami and trunk.

F. S., a man aged 52, had spent the greater part of three years preceding the operation in the hospital because of daily attacks of angina pectoris. Since the onset he had suffered from five to ten attacks daily. They were partially relieved by nitrites but occasionally morphine was required. The attacks were initiated by a feeling of tightness in the throat and upper part of the chest that rapidly became painful. There was salivation, severe perspiration, oppressive abdominal distention and a fear of impending death. The pain then became agonizing and spread over the precordium and down the ulnar

distribution of the left arm. Palpitation, pallor, a rise in blood pressure and tachycardia were also observed. The attacks were precipitated by slight exertion or emotional stress, and frequently they occurred from the mere anticipation of an attack. He continually kept nitrite tablets on his person; he would not even go to the bathroom without them. For the last eight or nine years he had been suffering from a mild form of diabetes mellitus. This was discovered incidentally to an examination during a siege of pneumonia. Insulin had occasionally been employed, although dietary measures have usually been sufficient.

On examination the blood pressure averaged 150 systolic and 100 diastolic. The retinal as well as the peripheral vessels showed moderately advanced arteriosclerosis. Repeated electrocardiographic examinations gave definite evidence of advanced myocardial damage. On two occasions cardiac decompensation had occurred. The general examination was otherwise negative.

Since the history and examinations indicated that considerable degenerative changes in the myocardium had already taken place, I was somewhat dubious about recommending the operation. The patient, however, was desperate and even after I had explained the danger he still had no hesitancy about accepting the chance of relief. The operation was performed the following day, May 1, 1937. Through a left paravertebral incision a short section was taken from each of the third, fourth and fifth ribs. The parietal pleura was separated from the vertebral column, and the rami communicantes from the second to the fifth dorsal ganglion inclusively were destroyed by electrocoagulation. The sympathetic chain was then sectioned between the fifth and sixth dorsal ganglions.

After two weeks the patient was allowed out of bed but, because of severe myocardial damage, complicated by diabetes mellitus and hypertensive heart disease, was kept in the hospital an additional four weeks for observation. There was no return of anginal seizures. At the time of discharge, moderate exercise was recommended. By the end of four months he was walking from 2 to 3 miles a day. He has faithfully returned at monthly intervals for observation, and when last seen twenty months after operation there had been no return of anginal seizures.

Fig. 6.—Electrocardiograms taken April 27, the second postoperative day. Note particularly the return of the T wave in lead 1 toward normal compared to the record taken four days before.

Here was a patient who almost beyond question was suffering from an advanced degree of coronary sclerosis and most probably had had one or more attacks of coronary thrombosis but was able to obtain temporary relief from the nitrites. It therefore seems reasonable to assume that an abnormal action of sympathetic impulses, on the basis of the principle of reversed action, was responsible for attacks rather than simple

34. This case was cited in a preliminary report read before the California State Medical Association at Pasadena in May 1938.

narrowing of the lumen of the vessels from arteriosclerotic coronary disease presumably present. Moreover, the assumption that the reversed action of sympathetic impulses was responsible for the presumed coronary spasm during attacks seems justified, since the operation gave complete relief. Furthermore, coexisting disease which has been demonstrated in this case obviously was not a contraindication to the operation.

CASE 2.—Frequent attacks of angina pectoris in an elderly man for fifteen months. Temporary relief during seizures by nitrites. General arteriosclerosis, moderate hypertensive heart disease and at least one major attack of coronary thrombosis. Complete relief from seizures by preganglionic section of rami and trunk.

T. H., a man aged 72, had been suffering for the past fifteen months from attacks of distress in the upper part of the abdomen; they usually occurred after eating, exercise or emotional stress and left him in a state of exhaustion. In February 1938, one year after the onset, he suffered a more severe attack, which came on after a game of golf and an evening meal; it started as had the previous ones. The stomach "felt stuffed as though it were filled with mud"; about an hour after the onset pain in the chest developed which radiated into both arms, more markedly on the left side. A physician was summoned and morphine was administered for relief. After a few days the patient felt well except for persisting minor attacks. For these he took nitrite tablets, which gave relief. During the succeeding two months he suffered two additional severe attacks similar to the first; each time relief was obtained by taking nitrite tablets. During the past year the patient had lost 20 pounds (9 Kg.); he starved himself in attempting to prevent attacks.

The past history was of importance, since he had always been nervous and had occasionally suffered from what he called "nervous indigestion." As a young man he had suffered from "nervous spasm in the lower part of the rectum." The attacks had usually occurred while lying down and were relieved on sitting up. For the past five years he had suffered from an anxiety state and episodes of mental depression, during which time he had two "nervous breakdowns."

On examination April 21, 1938, he was poorly nourished; he was 6 feet (183 cm.) tall and weighed 128 pounds (58 Kg.). The pulse rate was 65 beats a minute, the temperature was 98.8 F., and the blood pressure was 150 systolic and 110 diastolic. There was generalized arteriosclerosis, and electrocardiograms repeatedly showed a deep inversion of the T wave in lead I. Roentgenograms of the chest and gastrointestinal tract were negative. The Wassermann reaction of the blood was negative; the blood urea was 16 mg. per hundred cubic centimeters. Routine examinations of the blood and urine were essentially negative. Since medical measures and rest had failed to control the attacks, operation was recommended.

Two days later the patient was admitted to the Hospital of the Good Samaritan for observation prior to operation. The following day electrocardiograms showed changes compatible with coronary disease (fig. 5). That afternoon the patient suffered a sudden attack of abdominal distress and distention; the heart rate became fast and there was a sensation of tightness and weight in the chest and throat; pallor and excessive perspiration on the forehead and upper extremities were observed, and nitrite tablets again afforded relief.

The next morning (April 25) a preganglionic ramisection was done on the left side; the rami communicantes from the second to the fifth dorsal segment of the spinal cord were destroyed by electrocoagulation, and then the sympathetic chain between the fifth and sixth dorsal ganglia was sectioned. During the operation the patient showed no evidence of cardiac embarrassment or other ill effects; Horner's syndrome was not produced.

On the second postoperative day another electrocardiogram was taken which showed the T wave in lead I to have returned toward the normal upright position (fig. 6). The patient's subsequent postoperative course was likewise uneventful. He was dismissed from the hospital at the end of four weeks. When

last seen eight months after the operation he had gained 30 pounds (13.6 Kg.), was taking exercise and had remained free from attacks.

Here again is a patient with angina pectoris and major complications, viz., coronary thrombosis and hypertensive heart disease, yet operation was accomplished without untoward effects and complete relief from the attacks was obtained. Of further interest was the almost immediate change in the electrocardiograms from a pathologic character one day before operation toward a normal character the second day after operation. Although this observation was striking, no conclusions were drawn because they would necessarily be speculative. Other patients having had similar studies made showed no change whatever in the electrocardiograms; however, complete relief from seizures was obtained. Finally, the management of this patient's psychiatric problem was greatly facilitated, not only because of relief from pain and anxiety concerning attacks but also because of improvement in his general physical condition.

SUMMARY

Eleven patients have been treated by the operation here described. There have been no deaths, and all have obtained complete relief from what had previously been desperate attacks of angina pectoris.

The operation is based on the assumption that in angina pectoris the sympathetic action on the coronary vessels is reversed, because of pathologic changes occurring about the myoneural junction; i. e., sympathetic impulses in such cases produce coronary constriction.

Other operations heretofore recommended in the surgical treatment of angina pectoris have given relief at the expense of postganglionic fibers or afferent fibers or both. Such postganglionic operations are subject to the same criticisms that have brought about discard of this type of operation in the surgical treatment of Raynaud's disease. Operations devised to relieve pain by the interruption of afferent pathways are only palliative measures; they remove the warning signal of an impending seizure but do not attack the patient's real trouble.

The operation here described is a preganglionic operation; the major portion of the afferent mechanism is left intact and thus the warning signal is not removed; Horner's syndrome is not produced, and the efferent pathways on the operated side are almost entirely interrupted. A complete interruption of the efferent pathways to the coronary system theoretically would necessarily involve a bilateral operation; however, operation only on the left side is all that has been required to give complete relief from attacks.

727 West Seventh Street.

A Truly Black-Skinned Child.—How this sorting out and recombination of the genes takes place is shown in our accompanying color-plate. We can see by this why a truly black-skinned child can be produced only if both parents carry some Negro-skin-color genes. This should dispose of the old superstition, common in yesterday's fiction, of how a woman with some hidden Negro blood, "passing" as white and married to a White, might give birth to a coal-black baby. Where a black baby does unexpectedly turn up, it can be taken for granted that (a) both parents have Negro ancestry or (b) that the parentage is doubtful. In reverse, it would be equally impossible for a Negress with hidden white blood to be mated with a full-blooded Negro and give birth to a white child.—Scheinfeld, Amram: You and Heredity, New York, Frederick A. Stokes Company, 1939.

CORNEAL EXAMINATION AND SLIT
LAMP MICROSCOPYIN DIAGNOSIS OF LATE CONGENITAL SYPHILIS,
ESPECIALLY IN ADULTS

JOSEPH V. KLAUDER, M.D.

AND

ALFRED COWAN, M.D.

PHILADELPHIA

A cornea once involved with interstitial keratitis caused by congenital syphilis presents, almost without exception, certain sequelae which persist for the rest of the patient's life. Although the characteristic signs of an old interstitial keratitis can often be detected by oblique illumination and ophthalmoscopic examination, a proper study should and often can be performed only by biomicroscopy. With the corneal microscope and slit lamp a diagnosis of old interstitial keratitis can invariably be made, regardless of the age of the patient. We believe that the importance of slit lamp examination in clinical syphilology has not been sufficiently emphasized. The changes observed may be the only evidence of congenital syphilis. Their presence in adults and old patients may explain the absence of the history of infection, and they may serve as a means of interpreting positive or weakly positive results of Wassermann or precipitation tests. In the presence of other signs of syphilis a diagnosis of old interstitial keratitis determines the status of infection—congenital syphilis—and therefore has an important bearing on treatment and prognosis.

Briefly, it may be stated that interstitial keratitis is characterized by an infiltration throughout the entire thickness of the cornea, particularly the middle and deep layers, by the formation of blood vessels in the superficial, middle and deep layers (fig. 1) and by the association with uveitis. When caused by congenital syphilis it is always bilateral. As a consequence both corneas remain more or less permanently scarred and vascularized.

It should be emphasized that in many cases of interstitial keratitis the cornea recovers to such an extent that the scarring may be so faint and the remaining blood vessels so few and small that they can be detected only by means of slit lamp microscopy. Furthermore, the location, character and extent of the corneal haze and of the vessels, which are often impossible to determine by the ordinary methods of examination, are extremely important in diagnosis of old interstitial keratitis. The remains of a previous uveitis may be and often are detected only by slit lamp microscopy.

Regardless of the extent of involvement of the cornea, it is possible to make an almost certain diagnosis of a previous interstitial keratitis in nearly every case and after any length of time. One experienced in slit lamp microscopy can generally differentiate other forms of interstitial keratitis from the syphilitic type. When caused by syphilis the cornea presents a classic slit lamp picture.

EXAMINATION OF THE CORNEAS OF PATIENTS
WITH OLD INTERSTITIAL KERATITIS

The corneas of 100 patients who had interstitial keratitis were inspected grossly, by oblique illumination, and were examined with the ophthalmoscope and

by slit lamp microscopy to demonstrate evidence of old interstitial keratitis. The patients were both children and adults. The age range was from 6 to 65 years. The majority were under 30. Ninety-three of the patients had been patients in Wills Hospital at the time their interstitial keratitis was active. Corneal examination for old evidence of interstitial keratitis was made on these former patients from one to twenty years after the onset of interstitial keratitis. For seven patients the interval was still longer, in some cases as long as fifty years. Some of these patients had no knowledge of ever having interstitial keratitis, but they were included in the series since they showed by slit lamp microscopy the classic picture of old interstitial keratitis.

The corneas were inspected grossly to determine the presence of opacities. Inspection by oblique illumination facilitated seeing corneal opacities. Ophthalmoscopic examination was performed with the plus 20 lens in order to see old blood vessels and corneal opacities, which are sequelae of interstitial keratitis. If blood vessels were not seen with the pupil undilated, examination was repeated after dilating the pupil. Dilatation may be necessary in order to see vessels present only toward the periphery of the cornea. In some cases corneal opacities not seen on gross inspection or by oblique illumination were visible only after the pupil had been dilated and examined with the ophthalmoscope

Fig. 1.—Section through the cornea as seen with a narrow slit of light in biomicroscopy. The direction of the vessels actually seen is perpendicular, not horizontal as is indicated in the drawing. The portion of the vessel that seems to terminate in front indicates the depth, or the plane of the cornea in which the vessels lie. In interstitial keratitis vessels lie in any deep plane.

when the eye was turned in different directions. Old blood vessels as seen through the ophthalmoscope appear as black threads against the red fundus reflex (fig. 2). They resemble scratches on a glass surface and are commonly referred to as brushlike. Usually they are numerous and are scattered throughout the cornea; at times they number only a few and, as aforementioned, are confined to the periphery. Of course other pathologic processes, notably interstitial keratitis of other than syphilitic origin, that are later evidenced by opacities and old blood vessels should be considered in differential diagnosis. Although it is not our purpose to discuss differential diagnosis, it may be briefly stated that the history, the location of the opacity and the arrangement of the vessels are differentiating features. Slit lamp microscopy may be necessary for differential diagnosis.

In the cases studied, the ordinary methods of examination, as far as they concerned opacities and old blood vessels, did not always confirm the microscopic view in

From the Wills Hospital.
Read before the Section on Dermatology and Syphilology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

the slit lamp examination. In this examination opacities were present that were not apparent on gross inspection and old blood vessels were seen that could not be seen with the ophthalmoscope.

With the plus 20 lens of the ophthalmoscope, old blood vessels could be seen in corneas that had or had not gross opacities. Ophthalmoscopic examination is therefore more reliable than is gross inspection in diagnosis of old interstitial keratitis. On the other hand, corneas that were grossly clear, and in which blood vessels or other faint sequelae of interstitial keratitis were missed when examined by the ophthalmoscope and by oblique illumination, presented by slit lamp microscopy aforementioned changes that justified a diagnosis of old interstitial keratitis. Slit lamp microscopy is therefore more reliable in diagnosis of old interstitial keratitis than is study by oblique illumination and the ophthalmoscope. We are unacquainted with reports of studies of slit lamp microscopy in patients with old interstitial keratitis as an aid in diagnosing congenital syphilis. It is well known that opacities resulting from interstitial keratitis may persist indefinitely, and ophthalmologists are cognizant of the fact that residual blood vessels usually remain permanently. Igersheimer¹ recorded the statement that folds in Descemet's membrane arising from descemetitis accompanying interstitial keratitis may remain for the rest of the patient's life, and Ronné,² in referring to corneal opacities, referred to "not a few cases where at a later stage, by the help of the residual maculae cornea, I have diagnosed congenital syphilis."

Case 1 concerns a 49 year old woman who presented the type of folds in Descemet's membrane to which Igersheimer referred. Other changes seen by slit lamp microscopy were regarded as diagnostic of interstitial keratitis.

CASE 1.—A Negro woman aged 49 came to the eye clinic on account of poor vision. She was married and had had one miscarriage; there were no living children. She was the third born of a family of four. Both eyes were "sore" at about the age of 7 and remained inflamed for about three months. She received only local treatment to the eyes. She had no knowledge of ever receiving antisyphilitic treatment.

She had no stigmas of congenital syphilis. On gross inspection both corneas showed scattered fine opacities and old blood vessels by ophthalmoscopic examination. The vision of the right eye with correction was 6/60 and of the left eye with correction was 1/60. The Wassermann reaction was 44—; the Meinicke reaction was 4 plus.

The diagnosis of old interstitial keratitis with uveitis was made by slit lamp examination. The corneas were thinned, irregular and hazed throughout with considerable increase in relucency in the posterior portions. There were numerous folds, wrinkles and ruptures in Descemet's membrane. There were numerous blood vessels in the cornea and precipitates on the posterior surface of the cornea. The iris was atrophied and showed a few small synechiae.

CLINICAL APPLICATION OF SLIT LAMP MICROSCOPY IN DIAGNOSIS OF CONGENITAL SYPHILIS

Slit lamp examination in diagnosis of old interstitial keratitis as evidence of congenital syphilis is of most value in the clinical examination of adults whose Wassermann or precipitation reactions are in some degree positive, without history of infection and with-

out other evidence of congenital syphilis. Such examination of children with stigmas of congenital syphilis and positive Wassermann reactions is of course not necessary. However, in such patients, in the absence of corneal opacity and of history of "sore eyes," slit lamp examination definitely determines whether the cornea has or has not been involved with interstitial keratitis.

The diagnosis of old interstitial keratitis by slit lamp microscopy is valid evidence of congenital syphilis.³ Of course a diagnosis of congenital syphilis in an adult interprets the positive Wassermann reaction and defines the status of infection, which is necessary for proper treatment of syphilis. This is illustrated in case 2, which concerns a 58 year old patient who had objective signs of tabes and a 4 plus Wassermann reaction. Slit lamp microscopy established the diagnosis of old interstitial keratitis. The administration of antisyphilitic treatment to this patient would be of questionable value.⁴

Fig. 2.—Blood vessels in the cornea after interstitial keratitis as they appear with the ophthalmoscope against the reflex light from the retina.

CASE 2.—A man aged 58 came to the clinic because of poor vision. He had always had poor eyesight and had worn glasses for many years. He was an only child. He remembered having sore eyes when a child but could not recall any details. He stated that he had never had a genital lesion. After a "blood" test ten years before he received injections in the arm at intervals for three months.

The pupils were unequal and irregular in outline. The right pupil was fixed to light. The left reacted slightly to light.

3. Interstitial keratitis occurring in acquired syphilis is extremely rare. Although it has been reported, we have never observed a case. Such of the reported cases as we reviewed we did not regard as valid since slit lamp examination was apparently not performed. Other conditions that resemble interstitial keratitis were therefore not definitely excluded. Igersheimer stated that when syphilis is acquired in early childhood symptoms characteristic of congenital syphilis may later appear. He held that in such patients interstitial keratitis first appears in adult or late adult life. Such occurrence is apparently included in the following statistics as to the ratio of interstitial keratitis in acquired and in congenital syphilis. Grounew stated that the ratio is 1:133; Igersheimer gave 1:247; and in Adamantiadis' series it was 3:1,000 (for further discussion see Igersheimer.¹ Granstrom, K. O.: Die Keratitis Parenchymatosa in späterem Alter, *Acta Ophth.* 12:122, 1934. Adamantiadis, B.: Kératite pustuliforme profonde et les diverses formes de la kératite parenchymateuse syphilitique acquise, *Ann. d'ocul.* 172:304 [April] 1935).

4. As a principle of treatment in patients with late congenital syphilis, it may be stated that the higher the age when the disease is first discovered, the less the indication for the administration of syphilitic therapy. The chief hazard of congenital syphilis is interstitial keratitis. After the age of 20 its incidence greatly decreases. The transmission of the infection from persons with congenital syphilis to their progeny—third generation syphilis—is rare. The prognosis of congenital syphilis in adults in relation to the occurrence of cardiovascular involvement and neurosyphilis is not pertinent, as it is for patients of the same age with acquired syphilis.

2. Ronné, Henning: Treatment of Tardive Congenital Syphilis Seen in Social Light, *Acta Ophth.* 12:215-219, 1934.

Gross inspection of the corneas showed faint opacities. The vision with correction was right eye 6/15, left eye 6/30. On slit lamp examination of the right eye the central portion of the cornea was gray with a moderate loss of smoothness. The posterior surface was thickened and fairly opaque and contained a number of old blood vessels deeply situated. Examination of the left eye showed essentially the same features.

The patellar reflexes were absent and the Romberg sign was positive. The patient presented no stigmas of congenital syphilis and had no subjective symptoms of tabs. The Wassermann reaction of the blood was 4 plus and the Meinicke reaction 2 plus. The spinal fluid examination yielded negative results in all phases.

With regard to the value of slit lamp examination in the study of adults, the following comments are pertinent. The incidence of congenital syphilis in the general population, as given by different writers, ranges from 0.5 to 3 per cent and the incidence of interstitial keratitis among patients with congenital syphilis ranges from 25 to 50 per cent.

It is a remarkable fact that many patients who have had interstitial keratitis cannot in later life remember ever having had "sore eyes." It is to be recalled that interstitial keratitis may occur as early as the age of 1 year and that it may pursue, even in the absence of treatment, a mild course, retrogressing without the occurrence of corneal opacities and without much impairment of vision.

Patient 3 had no knowledge of having had interstitial keratitis. There were no stigmas of congenital syphilis. The presence of corneal opacity suggested old interstitial keratitis. Slit lamp microscopy confirmed the diagnosis.

CASE 3.—A man aged 32 was seen by one of us (J. V. K.) in the surgical ward of a hospital. He had a fractured femur. The Wassermann test routinely conducted showed a 2 plus reaction. He denied ever having a genital lesion; he had no knowledge of ever having "sore eyes" or receiving antisyphilitic treatment or a previous blood test. He had no stigmas of congenital syphilis. On examination for evidence of syphilis a faint opacity of the cornea was noted. The diagnosis of old interstitial keratitis was made by slit lamp examination.

A considerable percentage of patients with congenital syphilis do not have any of the well known stigmas of their disease. In studies⁵ of such stigmas among patients with interstitial keratitis it was observed that 17.5 per cent had hutchinsonian teeth, 29 per cent had chronic periostitis of the tibia (saber-shaped, or Fournier's, tibia), 45.5 per cent had the physiognomy of congenital syphilis and 18 per cent had symmetrical serous synovitis (Clutton's joints). It is to be recalled that these stigmas are less likely to be recognized or are absent in adults. Clutton's joints are seen only in children. Hutchinsonian teeth may have been extracted, or their notched surfaces, through use, are less apparent. The physiognomy of congenital syphilis is less typical in adults, especially after middle age.

A number of patients with congenital syphilis attain adult life without evidence of their infection except a positive Wassermann reaction. Such patients deny all knowledge of infection. It is well known that patients with acquired syphilis may give no history of infection. A certain percentage, therefore, of adult patients whose Wassermann reactions are positive and who are without history of infection are congenitally syphilitic. In a certain percentage of this group corneal examination in

the manner herein discussed may be the means of diagnosing or confirming a diagnosis of congenital syphilis.

CASE 4.—A girl aged 10 was first seen in April 1937, with interstitial keratitis of the right eye which pursued a mild course. There were no stigmas of congenital syphilis. The Wassermann reaction was 4 plus. Antisyphilitic treatment was administered. Interstitial keratitis which subsequently appeared in the left eye was mild and of short duration.

Twenty-two months after the patient was first seen the corneas were grossly clear. A former opacity of the right cornea had disappeared. Small opacities confined to the upper portion of both corneas were visible only with the ophthalmoscope and with the pupil dilated. A few blood vessels were seen in the left eye. The vision in both eyes was 6/9 and the Wassermann reaction was still 4 plus.

On slit lamp examination of the right eye the posterior portion of the cornea, particularly in the center, was increased in relucency. Also in the posterior portion of the stroma there was an irregular area of thin opacities. There were some deep vessels above. The anterior chamber was clear. The iris was intact. Examination of the left eye showed essentially the same changes.

There are few reported studies showing how long the Wassermann reaction of patients with congenital syphilis remains positive. In Saul's⁶ series of eighty-one patients with old interstitial keratitis reexamined from thirteen to twenty-eight years later the Wassermann reaction of sixty-five was positive and of the rest negative.

In our observation of patients in late adult life with congenital syphilis for whom the diagnosis of old interstitial keratitis was made, the Wassermann reaction was variable. It ranged from negative to strongly positive. Apparently, therefore, the positive Wassermann reaction of congenital syphilis may remain positive throughout the patient's life in treated as well as untreated patients (cases 1, 2, 3, 6). On the other hand it may become negative even in the absence of treatment. The following record of a case serves as an illustration:

CASE 5.—E. W., a white woman aged 27, unmarried, was the third child of a woman receiving antisyphilitic treatment in the clinic. The mother had had no miscarriages or stillbirths. She had three sons and a daughter (E. W.) who had "sore eyes" when a child. Both the daughter's eyes were involved for about a year and apparently only local treatment was administered. The patient was frail and underweight. She had no subjective complaint and had no knowledge of ever having received antisyphilitic treatment. There were no stigmas of congenital syphilis. The Wassermann and Meinicke reactions of her blood were negative. Diagnosis of old interstitial keratitis was made by slit lamp examination. This examination showed old blood vessels running from the limbus toward the center of the cornea, through which blood was circulating. There were numerous scattered punctate deposits in the deep layers of the cornea and a general haziness throughout.

One older and one younger brother showed no evidence of congenital syphilis on clinical and serologic examination.

The patient showed how benign a course congenital syphilis can pursue. Slit lamp microscopy definitely established old interstitial keratitis, which diagnosis was suggested by the history of "sore eyes" and the fact that her mother was syphilitic.

We believe that every patient who has had interstitial keratitis will subsequently present, probably permanently, a diagnostic picture of old interstitial keratitis by slit lamp examination. This picture constitutes in one sense a stigma of congenital syphilis.⁷

6. Saul, Hugo: Ueber das Schicksal der Patienten mit Keratitis parenchymatosa, *Ztschr. f. Augenh.* 86: 199 (June) 1935.

5. Klauder, J. V., and Robertson, H. F.: Symmetrical Serous Synovitis (Clutton's Joints), Congenital Syphilis and Interstitial Keratitis, *J. A. M. A.* 103: 236-240 (July 28) 1934.

7. What are popularly called the stigmas of congenital syphilis refer fundamentally to structural changes of a permanent nature such as hutchinsonian teeth and saber-shaped, or Fournier's, tibia. According to this concept Clutton's joints and ocular changes caused by interstitial keratitis would not be included.

Patient 6 presented on gross and ophthalmoscopic examination evidence of old interstitial keratitis, more definitely revealed, however, by slit lamp microscopy.

CASE 6.—A man aged 65 complained only of poor vision, for which he came to the clinic for refraction. He was the oldest of a family of seven, of whom six were living. His wife had had many miscarriages but only one child, who died at the age of 3. He stated that he had never had a genital lesion. He had no knowledge of having "sore eyes" when a child or of ever having received antisiphilitic treatment.

Results of the general physical examination were essentially negative. The teeth were absent. There were no stigmas of congenital syphilis. Both corneas on gross inspection showed faint opacities and old blood vessels by ophthalmoscopic examination. The vision of the right eye was 6/30, with correction 6/21, and of the left eye 6/60, with correction 6/30. Positive diagnosis of old interstitial keratitis was made by slit lamp examination. Throughout the entire corneas of both eyes there were opacities of varying densities, particularly in the upper portions. There were some deep blood vessels. The aqueous was clear and the iris was intact.

Repeated examination of the blood showed a 1 plus and a 2 plus Wassermann reaction and a 2 plus Meinicke reaction.

The clinician and the syphilologist should be conscious of the cornea and the sequelae of interstitial keratitis as herein discussed when examining children and adults suspected of having or known to have syphilis. Inspection of the cornea for opacity, even though faint, of which the patient may not be cognizant, and examination by oblique illumination and also with the plus 20 lens of the ophthalmoscope are clinical procedures easily conducted. These examinations may suggest the more valid means of diagnosing old interstitial keratitis—slit lamp microscopy. In the exclusion of congenital syphilis in a patient of any age, examination is not complete unless slit lamp microscopy has been performed. A negative outcome of this examination is evidence that the patient has not had interstitial keratitis, though of course it does not prove the absence of congenital syphilis.

1934 Spruce Street—1930 Chestnut Street.

ABSTRACT OF DISCUSSION

DR. JAMES R. DRIVER, Cleveland: The paper of Drs. Klauder and Cowan brings to our attention an important diagnostic method for the recognition of certain eye symptoms in late congenital syphilis. The use of the slit lamp in the examination of the cornea in syphilitic patients is of course not new. However, I agree with the authors that in the past this procedure has been neglected by syphilologists. I know of no textbook on syphilis that mentions or recommends its use. We as syphilologists must depend on the ophthalmologists for the examination and largely the interpretation of these observations. We have here an example of the importance of the close cooperation which the syphilologist must have with all other branches of medicine if the best in diagnosis and treatment of syphilitic patients is to be achieved. For two years at the University Hospital in Cleveland we have been using slit lamp microscopy as a routine procedure in the examination of all cases of congenital syphilis and in suggestive cases. More than sixty cases of congenital syphilis have been examined so far. In discussing the work with Dr. L. V. Johnston, who has made all of the examinations, I find that he agrees with the authors that (1) there are instances in which it was possible to make a diagnosis of old healed interstitial keratitis when oblique illumination and ophthalmoscopic examination failed to reveal its presence and (2) the picture of old interstitial keratitis as seen by the slit lamp is almost pathognomonic of the disease. The authors brought out, and I agree, that all patients with unexplained positive serologic tests either of the blood or of the spinal fluid should have their corneas examined by the slit lamp. In this way late congenital syphilis may be diagnosed in patients show-

ing perhaps no other stigmas of the disease. Of course, it is taken for granted that slit lamp examination simply supplements complete ophthalmoscopic study for other evidences of the disease in the eye. The paper deals only with the subject of late changes due to interstitial keratitis. I should like to mention that in our work with the slit lamp we have found its use valuable in giving a prognosis for patients showing active interstitial keratitis. Parents, guardians or social agencies want to know whether the individual so affected will be able to see. Plans for the future must often be made in advance. Now, since the character and severity of the disease can best be determined by slit lamp examination, this becomes easier. We have found that in several cases in which the cornea is thickened, owing chiefly to edema, even in the presence of much exudate the prognosis is good provided there is not extensive vascularization of the cornea.

DR. JOHN McLEOD, Kansas City, Mo.: At the clinic for congenital syphilis in the Children's Mercy Hospital in Kansas City we have used the slit lamp in a large number of cases as an aid in the diagnosis and prognosis of congenital syphilis. We have found that slightly vascularized opacities offer much better prognosis than those more heavily vascularized. It must be remembered that treatment of interstitial keratitis by hyperpyrexia may produce complete clearing of the cornea in occasional cases, so that even in a relatively short time thereafter no traces are evident. Rigorous slit lamp examination of the cornea six months after the subsidence of the disease may show absolutely nothing. In most cases there are associated with the keratitis certain other ocular stigmas, of some of which a directly syphilitic origin is uncertain. Among these may be mentioned the filming or veiling of the iris, described by Lemoine in 1934, consisting of a very fine veil, probably of connective tissue, over the entire iris and filling up the crypts. This is common in interstitial keratitis and in juvenile tabetic dementia paralytica, the type of patient in which one sees an enlarged vertically oval pupil fixed to light and accommodation but reacting to drugs. Our records, dating back to about 1916, show an incidence of interstitial keratitis of something over 5 per cent. In 24 per cent of these, I think, the spinal fluids have been positive. In practically all there has been some other ocular stigma of syphilis: typical syphilitic chorioretinitis, veiling of the iris, adhesions between the iris and lens or some of the minor fundus changes. These minor fundus changes vary from the so-called salt and pepper fundus on up through the peripheral chorioretinitis which is frequently associated with interstitial keratitis and, on the other hand, downward to almost complete normality, with a little more than normal pigmentation around the periphery of the retina. In using the slit lamp for the diagnosis of syphilis, one must bear in mind that tuberculosis produces a keratitis which may in its late stages resemble closely syphilitic interstitial keratitis. The recommendation for the use of the slit lamp as an aid in diagnosis of old congenital syphilis is excellent, but its use should be combined with a complete ophthalmoscopic and perhaps perimetric examination of the eye as well.

DR. JOSEPH V. KLAUDER, Philadelphia: The slit lamp should be used in study of all cases of interstitial keratitis. In fact, I think it is the court of final appeal in the diagnosis of the disease. I do not believe that the diagnosis of interstitial keratitis can be made in 100 per cent of cases by other methods. That has been apparent in the number of cases we see at the Wills Hospital in Philadelphia. I do not believe that slit lamp microscopy in the acute stage of interstitial keratitis is always helpful in making a prognosis. It is well known that opacities in the acute stage disappear to a variable degree, at times to a considerable degree, so that the end result is unexpectedly good. Poor vision after interstitial keratitis does not alone concern residual blood vessels or opacities, of course excepting leukoma. An important factor is the disturbance of the normal contour of the anterior and posterior surfaces of the cornea. Patients in adult life frequently do not recall their interstitial keratitis of childhood. The absence of history of "sore eyes" may not have any significance. Moreover, it is thought by some that interstitial keratitis may occur in intra-uterine life. It would be interesting to examine by slit lamp microscopy the oldest child of parents with syphilis. I say the oldest child, since interstitial keratitis is more likely to appear in the first born.

CARDIAC ASTHMA AND ACUTE PULMONARY EDEMA COMPLICATING TOXEMIAS OF PREGNANCY

FURTHER OBSERVATIONS

DUNCAN E. REID, M.D.

AND

HAROLD M. TEEL, M.D.

BOSTON

Recently we called attention to an interesting and dramatic symptom complex which occasionally complicates the severe nonconvulsive toxemias of pregnancy.¹ It is characterized by the sudden appearance in a previously comfortable patient of extreme orthopnea, dyspnea, cyanosis and cough productive of frothy and often pinkish sputum. Numerous crepitant rales appear with the onset of the attack, and they persist, at least in the lung bases, for a variable period thereafter.

Attacks have usually occurred in patients while at rest in bed. They closely resemble severe attacks of cardiac asthma such as occur characteristically in non-pregnant persons with conditions that impose a burden on the left ventricle, notably severe hypertensive disease, aortic insufficiency and nephritis with hypertension.

We referred to this complication of nonconvulsive toxemias of pregnancy as "cardiac asthma and acute pulmonary edema." It has been encountered only in patients with severe toxemia. Hypertension, albuminuria and edema, all of marked degree, were present in all cases for two or more weeks preceding the first seizure.

In our original report, the suggestion was made that the mechanisms of origin of the pulmonary edema in these cases and in eclampsia were similar or identical and that this mechanism is essentially left ventricular heart failure. It was also pointed out that a background of vascular hypertension is often found in toxemic patients who develop this symptom complex. However, six cases were reported in which cardiac asthma and acute pulmonary edema complicated simple acute preeclampsia without a background of cardiovascular or renal disease.

During the past two years we have had subsequent opportunity to observe a number of toxemic patients in whom this complication has developed. In this communication we present certain observations on the clinical nature and pathologic physiology of such attacks, as illustrated by several case histories. In contrast to the cases previously reported, these patients had backgrounds of some degree of hypertensive disease, although none have had attacks resembling paroxysmal dyspnea or cardiac asthma except during the latter half of pregnancy, when the superimposition of toxemia of pregnancy resulted in exaggeration of the hypertension with the appearance of generalized edema.

That the increase in hypertension accompanied by the appearance of marked albuminuria and edema in these patients indicated the superimposition of preeclampsia on hypertension, rather than renal insufficiency or progression of their vascular disease, is indicated by the observation that none of them had

significant azotemia and all were able to concentrate urine normally. That we are justified in terming the condition preeclampsia is also indicated by the fact that, coincident with the attacks, these patients showed the marked sudden changes of hemoconcentration and other conditions found on laboratory examination which are characteristic of this disease. In one of these cases, after repeated severe attacks of cardiac asthma with acute pulmonary edema there developed severe headache, temporary amblyopia, torpor and marked rapid hemoconcentration following a typical eclamptic convulsion. We present this patient's history in some detail:

CASE 1.—K. C., aged 39, was admitted to the Boston Lying-in Hospital Nov. 3, 1937, in the twenty-ninth week of her eleventh pregnancy with the history of three severe attacks of paroxysmal dyspnea and manifestations of marked hypertension, albuminuria and edema.

The family history revealed that her mother and one sister had hypertension.

There was nothing in the past history to suggest glomerulonephritis or pyelonephritis. There had been ten previous pregnancies, of which the first four were entirely normal. The last six pregnancies had been complicated by mild asymptomatic hypertension without significant albuminuria or edema. The maximum blood pressure recorded was in the fifth pregnancy, when it was once found to be 160 systolic and 110 diastolic. The sixth pregnancy ended in spontaneous abortion, but all others ended in term deliveries of large live babies.

The patient has been examined between pregnancies three times in this clinic during the last seven years. At these examinations the blood pressure was found to be from 140 to 150 systolic and 100 diastolic. Except for slight obesity, there were no other abnormalities. At each examination the urine contained no albumin. Her subjective health had been excellent with no cardiovascular or renal symptoms, in spite of the fact that she did all the housework for a family of nine.

The last menstrual period began April 15, 1937. Except for a little more than usual nausea and vomiting during the second month, this pregnancy progressed asymptotically up to the twenty-fourth week, when the patient first noticed edema involving the face, hands and feet. When the edema had persisted for about two weeks, she began to drink large amounts of water, up to twelve or more glasses a day, on the advice of a friend who was a nurse. Several days after the adoption of this policy she was awakened at 4 o'clock in the morning with a severe and frightening choking sensation. The attack was characterized by extreme orthopnea and dyspnea, cough and difficulty with expiration. "I had to sit up to get my breath. A wall seemed to come right up over my chest and I couldn't breathe. It seemed as if each breath would be my last." The acute distress lasted some two hours, during which time members of the family tried to persuade her to lie down, but she "had to sit up." She remained in bed for twenty-four hours, after which she resumed her duties about the house. The forcing of fluids was discontinued for about a week, because the patient was afraid to resume it, having associated it with her attack of cardiac asthma. However, at the insistence of her family and the nurse, the forcing of fluids was resumed. After several days there was a second attack, which came on while she was resting about an hour after dinner. This episode was essentially like the first one, but it was some five hours until the extreme dyspnea and orthopnea were gone. The next day the patient was up and about again. Indeed, she stated that she was afraid to go to bed or lie down. Five days later there was a third attack. This time she sat in a chair with her head resting on a table for the first hour. She found this position decidedly more comfortable. Next day she reported to the clinic for the first time.

The patient was large, well developed and dyspneic, with moderate generalized edema. There was no cyanosis, and the heart moderately enlarged and the rhythm normal and there was a systolic murmur over the precordium. The blood pressure was 230 systolic, 160 diastolic. Auscultation of the lungs revealed numerous crepitant rales at both bases, extending above the

From the Department of Obstetrics of Harvard Medical School and the Boston Lying-in Hospital and the Department of Child Hygiene of the Harvard School of Public Health.

1. Teel, H. M.; Reid, D. E., and Hertig, A. T.: Cardiac Asthma and Acute Pulmonary Edema. Complications of Nonconvulsive Toxemia of Pregnancy, Surg., Gynec. & Obst. 64: 39 (Jan.) 1937.

midscapular and midaxillary regions. The liver was neither enlarged nor tender, and the uterus was consistent in size with a scant seven months pregnancy. The urine showed 4 plus albumin.

The patient was admitted to the hospital and placed on a regimen of fluid restriction, and digitalization was begun. There was a mild attack of cardiac asthma the first night. Although she lost 6 pounds (2.7 Kg.) during the first twenty-four hours, rales persisted at the lung bases. On the second hospital day, a 7 foot x-ray plate of the chest showed the heart considerably enlarged in its transverse diameter and diminished radiance of both lung bases with haziness of the costophrenic angles.

The vital capacity, as determined on the second hospital day after subsidence of the acute seizure, was 1,700 cc.² Retinoscopy revealed blurring of the disk margins and patches of "cotton wool" exudate. The arteries were constricted and the veins overfilled, but there were no hemorrhages.

On the morning of the third hospital day, the patient awakened with severe frontal headache and blurred vision. The condition grew worse, and in the afternoon she became irrational. A lumbar puncture was done, and clear fluid under 300 cm. of water pressure was obtained. Withdrawal of 30 cc. reduced the pressure below 150 cm. of water.

Forty minutes following the lumbar puncture there was a typical eclamptic convulsion. Magnesium sulfate given intravenously resulted in prompt improvement, and repetition controlled the patient's irritability and symptoms. Forty-eight hours later labor was induced and a stillborn 2 pound 1 ounce infant (935 Gm.) was delivered spontaneously. Subsequent recovery was rapid; within three days the lungs were free from rales and the vital capacity had risen to 2,700 cc. At the time of her discharge from the hospital on the fourteenth postpartum day there was neither dyspnea nor orthopnea, the blood pressure was 160/100, the urine contained 1 plus albumin, and the vital capacity was 2,850 cc.

This patient has been seen several times during the six months since delivery. She has no cardiac, vascular or renal symptoms and has resumed all the housework for a family of nine. The blood pressure is 140 systolic, 90 diastolic and the urine is free from albumin. Repetition of the 7 foot x-ray plate of the heart shows no enlargement in the transverse diameter, although there is a slight aortic knob.

The maximum value for nonprotein nitrogen in the blood was 40 mg. per hundred cubic centimeters ante partum and 43 mg. one week post partum. Blood uric acid ante partum was 4 mg. per hundred cubic centimeters. Of considerable interest is a sudden change in hemoconcentration, which occurred at the time of the convulsion. The hematocrit reading a few hours before the convulsion was 29.99 per cent. Shortly after the convulsion the hematocrit reading was 39.50 per cent. At the time of her discharge from the hospital fourteen days post partum the hematocrit and hemoglobin values were respectively 34.37 per cent and 10.4 Gm. We have repeatedly observed these sudden marked shifts in hemoconcentration in other patients with eclampsia, particularly when complicated by pulmonary edema.

This patient's history is presented to illustrate the occurrence of severe cardiac asthma with acute pulmonary edema as a complication of preeclampsia superimposed on mild asymptomatic hypertensive disease. That the marked increase in blood pressure, edema and albuminuria were fairly interpreted as preeclampsia was confirmed by the facts that the patient subsequently had a typical eclamptic convulsion without evidence of renal

failure and that she recovered promptly following termination of the pregnancy. We would emphasize that the patient has never suffered from cardiac symptoms and has never had an attack suggestive of nocturnal or paroxysmal dyspnea before or since the pregnancy described.

The specificity of pregnancy toxemia in causing cardiac asthma with acute pulmonary edema in a previously and subsequently well compensated hypertensive patient is better illustrated by the following case:

CASE 2.—F. M., aged 38, was admitted to the hospital in the fifth month of her ninth pregnancy because of severe hypertension, edema and history of recurrent attacks of paroxysmal dyspnea for two weeks.

The patient was known to have had an elevated blood pressure for at least six years. Her last pregnancy eighteen months before had been terminated in the sixth month in another hospital because of a severe toxemia of pregnancy complicated by seizures of dyspnea and orthopnea. Recorded conditions prior to termination of the pregnancy were essentially massive peripheral edema, numerous crepitant rales, a blood pressure of 260 systolic, 140 diastolic, and 4 plus albumin in the urine. Following termination of the pregnancy there was prompt improvement with disappearance of dyspnea, albuminuria and edema and decrease in blood pressure.

At repeated examinations during the eighteen months between this pregnancy and the present one, the blood pressure ranged from 180 to over 200 mm. of mercury systolic, but there was no edema, and there had been no further seizures of dyspnea and no other symptoms referable to the heart.

The present pregnancy had progressed without incident until two or three weeks before examination, when generalized peripheral edema appeared. Some days later the patient began to have recurrent seizures typical of cardiac asthma with cough productive of frothy sputum.

Examination revealed essentially peripheral edema, dyspnea, cardiac enlargement, numerous crepitant rales over the lower lobes of both lungs and a blood pressure of 240 systolic, 160 diastolic. The urine did not contain albumin.

The patient was placed on a regimen of restricted fluid intake and digitalized, and the pregnancy was terminated by abdominal hysterotomy and sterilization. There was rapid marked improvement with disappearance of peripheral edema, dyspnea and signs of pulmonary edema and decrease in blood pressure. The patient was discharged seventeen days post partum with no signs or symptoms of cardiac decompensation.

The patient has been followed for eighteen months since delivery. The blood pressure ranges from 180/110 to 240/120 and she has considerable headache, but the lung bases have remained clear and she has had no recurrence of the seizures of paroxysmal dyspnea.

This patient is the only one in our series without marked albuminuria who has had typical cardiac asthma appear for the first time as a complication of toxemia of pregnancy. It should be added that her antecedent hypertensive disease was the most marked of any patient in the series. The point of particular interest to us is that, although she is known to have had marked hypertension for six years, she has never suffered from seizures of cardiac asthma or pulmonary edema except as described in the last two pregnancies, when marked increase in blood pressure, edema and (in the first pregnancy) albuminuria indicated the superimposition of preeclampsia.

The third case illustrates the futility of prolonged expectant treatment when attacks of cardiac asthma with acute pulmonary edema have occurred in the course of severe toxemia of pregnancy.

CASE 3.—M. B., a quintipara aged 37, was transferred from another hospital to this clinic in the thirty-sixth week of pregnancy because of toxemia complicated by marked choking sensations, dyspnea and orthopnea.

2. We have determined the vital capacity on a number of these patients with immediate cardiac asthma or between attacks. The procedure is the maximum, and the first effort invariably gives the maximum. In one subject an immediate seizure of cardiac asthma with acute pulmonary edema followed determination of the vital capacity.

She was known to have had some degree of toxemia with her last two pregnancies. Her family physician knew that her blood pressure was definitely above normal early in the present pregnancy. In the seventh month of pregnancy there was a definite increase in the blood pressure, with the appearance of edema of the lower extremities and albuminuria. Simultaneously the patient began to have attacks of nocturnal dyspnea and was obliged to lead a bed and chair existence. On admission to a private hospital two weeks later the blood pressure was 200 plus systolic and from 100 to 120 diastolic, and the urine

showed 4 plus albumin. Over a period of two weeks she was observed by her physician to have several attacks of nocturnal dyspnea during which the chest was full of fine and coarse rales. She was digitalized.

On admission to this hospital, physical examination revealed the following: The patient was frail, with marked orthopnea and cyanosis. There was only a slight degree of peripheral edema. The blood pressure was 220/140 and there was marked sclerosis of the

The patient was large and edematous, weighing 214 pounds (97 Kg.), and had moderate cyanosis. The blood pressure was 194/118. Auscultation of the chest revealed fine to coarse rales throughout. While the patient was being turned to facilitate examination, a severe attack of acute pulmonary edema developed. Several hours later the vital capacity was found to be 1,820 cc. Immediately following this procedure the patient was seized with a second similar attack of orthopnea and dyspnea, with marked exacerbation of pulmonary edema. A 7 foot x-ray plate of the heart taken at this time and repeated nine weeks post partum indicates the degree of pulmonary edema and cardiac dilatation associated with these episodes of acute pulmonary edema (figs. 1 and 2).

The urine contained 4 plus albumin. There were numerous white blood cells, occasional red blood cells and granular casts in the sediment. Chemical examination of the blood was negative except for a total protein value of 5.77 Gm. per hundred cubic centimeters.

The patient was given morphine in liberal doses. Fluids were restricted and she was rapidly digitalized. She was delivered by cesarean section twenty-four hours later. The baby weighed 5 pounds 5 ounces (2,410 Gm.) and survived. The mother's condition improved rapidly. There were no subsequent attacks of pulmonary edema, and one week later her chest was clear. The vital capacity two weeks post partum had risen to 2,540 cc.

The patient has been followed for two years since delivery and has shown a progressive increase in blood pressure with albuminuria. Only within the past two months have attacks of paroxysmal dyspnea recurred, and subjectively they are of the same character as those which the patient experienced for the first time when pregnant.

Studies of the vital capacities and hemodynamics of these patients show changes similar to those reported in classic cardiac asthma. All showed a marked decrease in the vital capacity, which increased rapidly with clinical improvement following delivery. Changes in the cell volume as determined by hematocrit readings indicate marked hemoconcentration associated with the seizures. Peripheral venous pressure and circulation time⁴ were found to be within the upper limits of normal.

Although, as we have pointed out, cardiac asthma and acute pulmonary edema may complicate simple acute preclampsia in patients without a background of hypertensive or renal disease, this symptom complex is more commonly encountered when preclampsia is superimposed on such a background.

Our previous report dealt primarily with the complication in patients with simple preclampsia. In this study, on the other hand, some degree of vascular hypertension formed a background for the preclampsia in all cases.

We believe that general recognition of this complication of nonconvulsive toxemia is important for two

Fig. 1 (case 4).—Degree of pulmonary congestion and cardiac dilatation at the height of an attack of "cardiac asthma."

retinal vessels. The heart was enlarged and the lungs were full of rales. The vital capacity was 1,500 cc., and the hematocrit reading was 42.59.

Some twenty-four hours after admission (during which interval several attacks of paroxysmal dyspnea had been observed), labor was induced by artificial rupture of the membranes. Several hours later she delivered a living baby normally. Her condition was only fair for several days post partum. There was one rather mild attack of pulmonary edema on the tenth postpartum day. However, two weeks following delivery the vital capacity had risen to 2,280 cc. and the hematocrit reading had decreased to 33.50.³ She was discharged much improved with the blood pressure still 190/110.

She has been observed for two years following delivery. She has had no subsequent attacks of paroxysmal dyspnea and she is able to do light housework with no discomfort. The blood pressure at the last observation was 220/114. The urine is free from albumin. She has been sterilized by x-rays.

Although this patient was reasonably well treated by bed rest, restriction of fluid intake and digitalization, the attacks persisted and tended to become worse during the three weeks until the pregnancy was terminated. We have had similar experience with other patients observed and treated for shorter periods.

The final history to be reported here is that of a primipara about whose blood pressure we have no information prior to or early in pregnancy. From her physical examination at the time of the attack and her subsequent course we suspect that there was antecedent hypertension.

CASE 4.—D. W., a primigravida aged 33, entered the hospital for emergency treatment in the thirty-eighth week of pregnancy. Her complaints were dyspnea, orthopnea and swelling of the lower extremities. The past and family histories were non-contributory. It is known that at examination six years previously the urine contained no albumin, the sediment was negative and the specific gravity was 1.030.

3. The cell volume two weeks post partum (33.50 per cent) is considerably lower than that obtained during the seizures of dyspnea before delivery (42.59 per cent). Ordinarily the cell volume increases considerably following delivery. This marked reversal of the usual trend indicates that there was considerable hemoconcentration associated with the seizures of cardiac asthma.

Fig. 2 (case 4).—Appearance nine weeks after delivery.

4. Venous pressure was determined by the method of Moritz and von Tabora (Ueber eine Methode, beim Menschen den Druck in oberflächlichen Venen exakt zu bestimmen, Deutsches Arch. f. klin. Med. 98: 475, 1910) and the circulation time by the method of Robb and Weiss (A Method for the Measurement of the Velocity of the Pulmonary and Peripheral Venous Blood Flow in Man, Am. Heart J. 8: 650 [June] 1933).

reasons: First, its frequency is greater than is generally appreciated.⁵ It is one of the more common immediate causes of death from nonconvulsive toxemia. Its early recognition combined with suitable therapy will aid in reducing the mortality in nonconvulsive toxemia. Second, consideration of the probable similarity in the mechanisms of origin of cardiac asthma with acute pulmonary edema in the nonconvulsive toxemic patient and acute pulmonary edema in the eclamptic should lead to more rational and effective therapeutic protection of the heart in eclampsia.

We have found no cause to modify our original view that the immediate cause of the symptom complex is left ventricular heart failure. We would point out that, in general, marked degrees of acute pulmonary edema more often accompany the seizures in patients with preeclampsia than in nonpregnant hypertensive patients with cardiac asthma. In addition, in most instances signs of pulmonary edema persist between attacks until delivery is accomplished. The increased capillary permeability, edema and low serum proteins which are characteristic of preeclampsia would appear to offer a reasonable explanation for this difference.

Immediate treatment of the acute seizures involves the use of morphine in large doses, and venesection or peripheral venostasis if pulmonary edema is marked. After a brief period, temporary improvement is the rule. However, from knowledge of the clinical courses of some fifteen cases we have come to the conclusion that prolonged expectant therapy, even including suitable cardiac measures, is undesirable. Once the patient has had such attacks, the improvement has been temporary and recurrence of attacks is the rule until the patient is delivered. For this reason termination of the pregnancy by suitable means is desirable when the patient has been prepared by preliminary fluid restriction and full digitalization. This should be a matter of from twelve hours to, at the most, three or four days.

Again, it must be emphasized that the immediate prognosis must be guarded in undelivered patients in whom this symptom complex develops. Death may occur during the attack. However, it is equally important to realize that, once such patients are successfully delivered, the outlook is not a dismal one. The occurrence of such attacks in the presence of pregnancy cannot be regarded as evidence of the rapidly progressive vascular disease which it denotes in the nonpregnant, but rather of a temporary removable burden to the vascular system produced by the toxemia of pregnancy. In our experience these patients, with one exception, have continued to enjoy relatively normal lives without recurrence of the attacks described.

SUMMARY AND CONCLUSIONS

Nonconvulsive toxemia of pregnancy characterized by marked hypertension, albumin and edema is occasionally complicated by sudden left ventricular heart failure, as indicated by seizures of cardiac asthma with acute pulmonary edema. Both patients with previously normal vascular and renal systems and with antecedent hypertension may have such attacks, although they are more common in the latter. Once such attacks have occurred, lasting improvement is not to be expected until the pregnancy is terminated.

5. In a recent report of a fatal case of nonconvulsive pregnancy toxemia by Harrison and his associates, acute pulmonary edema would appear to have been the immediate cause of death (Harrison, D. A., Jr.; Shelton, J. H., and Carrithers, C. M.: Postmortem Cesarean Section in Twin Pregnancy, with Delivery of Two Living Babies, *J. A. M. A.* 110: 2066 [June 18] 1938).

Therapy consists in large doses of morphine with venesection, or in peripheral venostasis when indicated by severe pulmonary edema, followed by rapid digitalization and dehydration and delivery within a few days.

The immediate prognosis is grave, but if delivery is survived the ultimate prognosis is good.

We believe that the distressing pulmonary edema often encountered in severe and fatal eclampsia is also a result of acute left ventricular heart failure. For this reason, rapid full digitalization of all eclampsia patients is indicated.

THE TREATMENT OF PULMONARY TUBERCULOSIS WITH SULFAPYRIDINE

STANTON T. ALLISON, M.D.

AND

ROBERT MYERS, M.D.

NEW YORK

The encouraging results of sulfanilamide therapy in infections caused by the hemolytic streptococcus, the meningococcus, the colon bacillus and the gonococcus, and the more recent results of sulfapyridine therapy in pneumococcal pneumonia have made us hopeful that eventually some such chemotherapeutic agent might be discovered which would influence the course of pulmonary tuberculosis in a favorable manner. The reports from England as well as those from America have indicated that sulfapyridine is an impressive drug, powerful in effecting a cure in pneumonia yet relatively nontoxic as far as permanent harm or death of the patient is concerned. We felt that this drug might have some bactericidal effect on the tubercle bacillus, and since there had been no reports on its use in treating tuberculosis we decided in December 1938 on the investigation which we are now reporting. Recently there has appeared in the literature a paper on the effects of sulfapyridine on experimental tuberculosis in the guinea pig by Feldman and Hinshaw.¹ These observers report that in their investigation sulfapyridine exerted a definite and striking modification and retardation of the expected course of experimentally induced disease. The most impressive effects were those related to the spleen. The spleens of the untreated animals presented without exception severe progressive tuberculosis, while those in the treated animals, with one exception, showed no gross signs of tuberculosis.

For the study of the action of sulfapyridine on the clinical course of pulmonary tuberculosis in human beings we agreed that certain requirements must be met in the selection of our cases. In the first place we decided that only cases presenting exudative processes with little tissue defect (cavity formation) would be used, since, it was argued, if these cases did not respond to the drug certainly it could be assumed that long standing cases of fibrocavernous phthisis would not respond. Secondly, it seemed wise to use only patients whose sputums were positive for tubercle bacilli at the time so that there would be no doubt in our minds of the diagnosis. It was further decided that this would

From the Tuberculosis Service, First Medical Division, Bellevue Hospital, and the Department of the Practice of Medicine, College of Physicians and Surgeons, Columbia University.

The sulfapyridine used in this work was supplied by Merck & Co., Inc. 1. Feldman, W. H., and Hinshaw, H. C.: Proc. Staff Meet., Mayo Clin. 14: 174 (March 15) 1938.

be a short period study to ascertain, if possible, the effects if any on the pulmonary process.

As the average adult pneumonia patient receives from 20 to 25 Gm. of sulfapyridine to effect a cure, it appeared reasonable to assume that in treating patients with pulmonary tuberculosis we should use from two to four times this amount over a longer period of time.

No attempt was made in our study to determine the blood level (estimates of sulfapyridine concentration in the blood).

REPORT OF CASES

CASE 1.—E. H., a man aged 49, a Russian, was admitted to Bellevue Hospital Dec. 30, 1938, with a history of cough of two months' duration productive of 150 cc. of thick gray, nonfoul sputum daily. At the onset of his illness there had been a hemoptysis of one half ounce (15 cc.) of blood, followed by streaking for several days. He had noticed some dyspnea and had had night sweats for several weeks. Hoarseness had been present for about the same period. He had had no chills and apparently no fever. His past history revealed that he had been a heavy drinker for the last five years. Fifteen years before he had had a primary syphilitic lesion for which he had received antisiphilitic therapy.

Examination of the chest revealed bilateral apical dullness, greater on the right, with bronchovesicular breath sounds over both apices. No rales were heard. The initial roentgenogram of the chest (Jan. 1, 1939) showed a mixed type process, but predominantly exudative, involving to some degree all the right lung but especially the upper half with a nodular distribution. No cavities were visible. The left lung showed a bronchiogenic spread to the first and second intercostal spaces.

The laboratory observations were as follows: The urine was normal. The Wassermann reaction of the blood was negative. Concentrated sputum was positive for tubercle bacilli.

A blood count Jan. 2, 1939, showed hemoglobin 87 per cent, red cells 4,910,000, white cells 7,150, polymorphonuclear leukocytes 74 per cent, lymphocytes 25 per cent and monocytes 1 per cent. On January 5 it showed white cells 11,200, polymorphonuclear leukocytes 72 per cent, lymphocytes 24 per cent and monocytes 4 per cent.

The patient was started on sulfapyridine 1 Gm. every four hours. He received a total of 57 Gm. in fourteen days.

After the second and third doses of the drug the patient complained of epigastric "burning" and nausea but there was no vomiting. This disappeared as soon as the drug was withdrawn and did not return when the drug was resumed two days later, although he did have slight dizziness. The temperature range was between 98 and 100.6 F. (rectally) during his stay in the hospital and did not appear to be affected by the drug. February 7 a second roentgenogram of the chest revealed no clearing of the tuberculous process. A third and final roentgenogram of the chest on February 27 revealed no essential change in the tuberculous process. Sputum examination continued to be positive for tubercle bacilli. The patient showed no improvement and was discharged to a sanatorium February 28, having been observed for two months.

CASE 2.—F. B., a man aged 27, a Filipino, was admitted to Bellevue Hospital Jan. 14, 1939, having been transferred from Mount Sinai Hospital. He gave a history of sudden onset of chills, fever, sweats and marked weakness two weeks before admission. There was slight cough with scanty white sputum. He had lost 15 pounds (6.8 Kg.) in the last few weeks. Recently he had noticed a tender swollen gland in the lower right anterior cervical region, which had been aspirated at Mount Sinai Hospital and culture of the pus reported positive for tubercle bacilli. The past history was irrelevant.

On examination the patient was thin and acutely ill, with rapid respirations, hot moist skin, a temperature of 105 F. (rectally) and pulse 130. The chest appeared normal except for harsh breath sounds throughout. No rales were heard. The spleen was palpable.

The initial roentgenogram of the chest January 14 revealed the finely nodular symmetrical infiltration evenly distributed from apexes to bases so characteristic of hematogenous miliary tuberculosis. The laboratory observations were as follows: The urine showed a trace of albumin. The Wassermann reac-

tion of the blood was negative. Concentrated sputum was negative for tubercle bacilli.

A blood count January 17 showed hemoglobin 65 per cent, red cells 2,970,000, white cells 11,300, polymorphonuclear leukocytes 80 per cent, lymphocytes 11 per cent and monocytes 9 per cent. On January 18 it showed white cells 10,800, polymorphonuclear leukocytes 70 per cent, lymphocytes 26 per cent, monocytes 3 per cent and eosinophils 1 per cent. On January 23 it showed white cells 11,200, polymorphonuclear leukocytes 68 per cent and lymphocytes 32 per cent.

The patient was given sulfapyridine 1 Gm. every four hours. He received a total of 18 Gm. in five days.

Twelve hours after sulfapyridine was started, the temperature dropped two degrees and the pulse was slightly lower. On the second day after sulfapyridine administration the patient complained of abdominal cramps and nausea. Shortly after this vomiting set in, and after the patient had received only 18 Gm. of the drug it was necessary to discontinue it. From then on the course of the disease was rapidly progressive to a fatal termination. Death occurred January 28, on the fourteenth day of his stay in the hospital. A roentgenogram of the chest taken the day before his death (January 27) revealed the process in the lungs to be more extensive, especially at the bases.

On postmortem examination hematogenous miliary tuberculosis was revealed in the lungs, the heart, the serous membranes, the spleen, the liver, the adrenals and the kidneys.

CASE 3.—S. M., a man aged 38, an Italian, was admitted to Bellevue Hospital Dec. 29, 1938, with the history of a rather sudden onset of chest cold three weeks before admission. He expectorated 1 ounce (30 cc.) of mucopurulent sputum daily and complained of right anterior chest pain of two weeks' duration and left anterior chest pain of three weeks' duration. There had been weakness and fatigue for two weeks, some anorexia and the loss of 5 pounds (2.3 Kg.) in weight. The past history was irrelevant.

Examination of the chest revealed dullness on the left from the apex to the fourth rib anteriorly and the fourth thoracic spine posteriorly, with a patch of medium moist rales and increased breath sounds in the posterior axillary line at the level of the seventh thoracic vertebra. The right side of the chest showed dullness to the fourth rib anteriorly and the fourth thoracic spine posteriorly with amphoric breathing at the apex. There was bronchovesicular breathing on the right from the infraclavicular region to the fifth rib and posteriorly to the sixth thoracic spine with medium moist rales over this area. The rales at the right apex had a consonating quality.

The initial roentgenogram of the chest December 30 showed a diffuse exudative infiltration involving the right upper lobe with multiple cavitations in the apical and subapical regions. The lower half of the right lung showed a diffuse, nondense, finely nodular infiltration. The left lung showed an exudative nodular infiltration below the first rib, particularly in the periphery of the second and third intercostal spaces.

The laboratory observations were as follows: The urine was normal except for a very faint trace of albumin. The Wassermann reaction of the blood was negative. Concentrated sputum was positive for tubercle bacilli. A blood count Jan. 2, 1939, showed white cells 8,800, polymorphonuclear leukocytes 76 per cent and lymphocytes 24 per cent.

The patient was given sulfapyridine 1 Gm. every four hours, but after receiving only 9 Gm. of the drug in three days he became so nauseated that he insisted on leaving the hospital.

CASE 4.—W. M., a man aged 44, Polish, admitted to Bellevue Hospital Jan. 9, 1939, had for seven months had a troublesome cough which had become productive of 1 ounce (30 cc.) of mucopurulent sputum daily in the last three weeks. There had been no hemoptysis. Hoarseness had been present for five weeks with slight pain on swallowing. The past history was irrelevant.

Examination of the chest revealed dullness in the infraclavicular areas, especially on the right side, with some degree of dullness over most of the right side of the chest. There were bronchovesicular breath sounds over most of the chest, front and back, with rales of all types. Consonating rales were heard in the right infraclavicular area.

The initial roentgenogram of the chest January 11 revealed extensive bilateral tuberculosis, chiefly exudative, with a pneumonic process involving the right upper lobe and a 5 by 6 cm. cavity at the right apex. There was a typical bronchiogenic miliary spread to the bases.

The laboratory observations were as follows: The urine was normal. The Wassermann reaction of the blood was negative. Concentrated sputum was positive for tubercle bacilli.

A blood count January 13 showed hemoglobin 85 per cent, red cells 4,980,000 and white cells 12,150.

January 14 it showed red cells 4,730,000, white cells 14,850, polymorphonuclear leukocytes 91 per cent and lymphocytes 9 per cent.

January 15, red cells 4,940,000, white cells 11,250, polymorphonuclear leukocytes 88 per cent and lymphocytes 12 per cent.

January 16, white cells 10,550, polymorphonuclear leukocytes 85 per cent and lymphocytes 15 per cent.

January 17, white cells 9,050, polymorphonuclear leukocytes 86 per cent and lymphocytes 22 per cent.

January 18, white cells 10,200, polymorphonuclear leukocytes 78 per cent and lymphocytes 22 per cent.

January 19, white cells 7,800, polymorphonuclear leukocytes 65 per cent and lymphocytes 35 per cent.

January 21, red cells 4,500,000 and white cells 10,000.

January 28, white cells 11,200, polymorphonuclear leukocytes 81 per cent and lymphocytes 19 per cent.

The patient was given sulfapyridine 1 Gm. every four hours and received a total of 108 Gm. in twenty-five days. After the first slight epigastric "burning," which was relieved by sodium bicarbonate, he had no ill effects from the drug in any way that we were able to determine. After receiving 6 Gm. of the drug his temperature fell from 103.6 to 101.6 F. and after 12 Gm. of the drug became normal. In spite of the continuance of the drug, however, the temperature from then on fluctuated between 101 and 101.6 F. A second roentgenogram of the chest January 26 showed that there was some spread of the tuberculous process at the bases; otherwise there was no change from the film taken January 11. Subsequent sputum tests were positive for tubercle bacilli. After a total of 108 Gm. of sulfapyridine had been given it was apparent from signs, symptoms, x-ray examinations and the sputum that the patient had not been benefited by the drug. He now appeared weaker and was transferred February 15 to Seton Hospital, where he died of tuberculosis March 13.

CASE 5.—C. V., a Puerto Rican woman aged 24, was admitted to Bellevue Hospital March 27, 1939, with the history of a productive cough of two weeks' duration. The sputum was not foul. There had been no hemoptysis. She had lately noticed sweats at night and thought that she had been feverish. The past history was irrelevant.

Examination of the chest revealed dullness and loud bronchial breathing over the upper half of the right lung with medium moist and a few crepitant rales over this area. Aside from some harsh breath sounds at the apex the left lung appeared clear.

The initial roentgenogram of the chest, March 28, revealed a dense pneumonic process from the right apex to the fourth rib, the base of the shadow being outlined by the interlobar fissure. There was slight rarefaction in the first intercostal space. The left lung showed an exudative infiltration in the second and third intercostal spaces.

The laboratory observations were as follows: The urine was normal. The Wassermann reaction of the blood was negative. Initial sputum was negative for tubercle bacilli but two concentrated specimens of sputum taken soon after this were positive, as were all subsequent specimens.

A blood count March 31 showed hemoglobin 60 per cent, white cells 12,160, polymorphonuclear leukocytes 89 per cent and lymphocytes 11 per cent.

On May 3 it showed hemoglobin 79 per cent, red cells 4,840,000, white cells 5,880, polymorphonuclear leukocytes 79 per cent and lymphocytes 21 per cent.

On June 2 it showed hemoglobin 64 per cent, red cells 4,130,000, white cells 10,800, polymorphonuclear leukocytes 82 per cent and lymphocytes 18 per cent.

The patient was given sulfapyridine 1 Gm. every four hours with no apparent effect on her temperature, which ranged between 101 and 103 F. After five days of sulfapyridine therapy the patient, having received a total of 19 Gm., complained of pain and tenderness over the region of the left kidney and she began to have hematuria. Sulfapyridine was stopped and soon the hematuria did likewise. She continued to have pain in the left costovertebral angle, and an intravenous pyelogram was made which showed incomplete filling of the pelvis of the left kidney. Cystoscopy was carried out, revealing an obstruction of the left ureter near the kidney pelvis. With considerable difficulty a number 5 catheter was finally passed to the kidney pelvis, resulting in a rapid flow of clear amber urine. Following this procedure the pain and tenderness in the left kidney region cleared up almost immediately and she had no more trouble in this respect. A second intravenous pyelogram after this cystoscopic treatment showed a normal functioning left kidney. It was thought that the ureteral obstruction was due to acetylsulfapyridine crystals settling out in the kidney pelvis and passing into the ureter, forming an impaction.

A second roentgenogram of the chest April 17 revealed a spread of the tuberculous process in the left second intercostal space and likewise to the right base. A roentgenogram of the chest May 15 showed that the process in the left lung had spread considerably since her previous examination. A roentgenogram of the chest May 26 showed that both entire lung fields were almost completely involved with the tuberculous process. The patient is still in the hospital as this paper is being written, and apparently within a few weeks this case will terminate fatally.

CASE 6.—C. S., a white woman aged 20, was admitted to Bellevue Hospital March 24, 1939, with a history of pleurisy on the left side one year before, following which she was apparently well until September 1938, when she began to cough and expectorated half a cupful of nonfoul sputum daily. She had noticed some loss of weight, some weakness and dyspnea in the last two months. The past history, prior to her pleurisy one year before, had been essentially irrelevant.

On examination the patient appeared thin and chronically ill. She had "shotty" cervical glands. The trachea appeared to deviate slightly to the right. There was right apical dullness, and medium moist rales could be heard from the right apex to the fourth thoracic spine posteriorly. The left side of the chest showed dullness from the apex to the fourth rib anteriorly and to the fourth thoracic vertebra posteriorly. Over this area there were bronchovesicular breathing and medium moist and a few coarse rales.

The initial roentgenogram of the chest, March 25, revealed a mixed type process, predominantly exudative however, in the right first intercostal space and below the fifth rib. The left lung showed an exudative infiltration and small cavitation in the second intercostal space and some involvement of the left base.

The laboratory observations were as follows: The urine was normal. The Wassermann reaction of the blood was negative. Concentrated sputum was positive for tubercle bacilli.

A blood count April 6 showed hemoglobin 85 per cent, red cells 4,950,000, white cells 7,400, polymorphonuclear leukocytes 70 per cent, lymphocytes 24 per cent, monocytes 4 per cent and basophils 2 per cent.

April 16, red cells 5,400,000, white cells 8,450, polymorphonuclear leukocytes 74 per cent, lymphocytes 11 per cent, monocytes 7 per cent, transitionals 7 per cent and basophils 1 per cent.

April 22, red cells 5,090,000, white cells 9,500, polymorphonuclear leukocytes 85 per cent, lymphocytes 12 per cent, monocytes 3 per cent and basophils 1 per cent.

April 27, white cells 8,600, polymorphonuclear leukocytes 72 per cent and lymphocytes 9 per cent.

The patient was given sulfapyridine 1 Gm. every four hours; she received 103 Gm. in twenty-three days.

After receiving sulfapyridine for two days she became nauseated and vomited and the drug was withdrawn for twenty-four hours. It was resumed without a return of her vomiting and with only slight nausea at times.

A roentgenogram of the chest taken April 7 showed no essential change from the film of March 25. One taken April 15 showed no essential change from the previous plates, but that taken April 28 showed considerable spread of the process in the left lower lobe. The sputum was still positive and the patient appeared to be going downhill rather rapidly. It was felt that in order to save the patient's life, if indeed this was possible, it was expedient to stop sulfapyridine, which had apparently done her no good after 103 Gm., and collapse the left lung at once. Accordingly this was done.

A roentgenogram May 13 showed approximately 20 per cent collapse of the left lung; the right lung showing no change. A roentgenogram of the chest May 31 showed 60 per cent collapse of the left lung with closure of the cavity in the second intercostal space. For the first time the contralateral lung showed some clearing. Although the sputum was still positive, the patient appeared better.

CASE 7.—F. S., an Irishman aged 33, was admitted to Bellevue Hospital March 22, 1939. He had been discharged from the Raybrook Sanatorium for Tuberculosis six years previously as having arrested pulmonary tuberculosis. Six months before admission to Bellevue a cough had developed productive of a copious of mucoid sputum daily. During the last few months he had lost 18 pounds (8 Kg.) and had night sweats. He entered the hospital because of recent onset of pain in the left anterior part of the chest, intensified by coughing and deep inspiration. His temperature on admission was 102. F.

Examination of the chest showed a respiratory lag on the left. There was tubular breathing with increased whispered and spoken voice from the second to the fourth rib on the left between the anterior and midaxillary lines. Over this area there were dullness and many fine rales. The right side of the chest showed a few scattered fine rales throughout.

An initial roentgenogram of the chest March 23 revealed a fine infiltration throughout the right lung with thickening of the pleura. The left lung showed some light infiltration at the apex and dense pneumonic infiltration from the second to the fifth rib.

The laboratory observations were as follows: The urine was normal. The Wassermann reaction of the blood was negative. Initial sputum was positive for tubercle bacilli. Sputum culture showed type V pneumococcus.

A blood count March 23 showed hemoglobin 100 per cent, red cells 3,290,000, white cells 15,920, polymorphonuclear leukocytes 86 per cent and lymphocytes 14 per cent. March 29 it showed white cells 8,090, polymorphonuclear leukocytes 77 per cent, lymphocytes 19 per cent and monocytes 4 per cent.

The patient was given sulfapyridine 1 Gm. every four hours. The temperature, which on admission had been 102 F., fell to 99 within forty-eight hours of starting sulfapyridine therapy. The patient became so nauseated and vomited so much that after taking 5 Gm. of the drug it was discontinued. A roentgenogram of the chest April 1 revealed some slight clearing of the pneumonic area in the left lung. The process in the right lung remained the same. Roentgenograms of the chest taken April 11, April 19 and May 4 showed progressive clearing of the pneumonic process in the left lung, with no change in the tuberculous process on the right.

It was believed that we were dealing with a case of pulmonary tuberculosis in which type V pneumococcus pneumonia of the left upper lobe had developed. This pneumonia cleared under sulfapyridine therapy but the tuberculosis was not affected. In this case even as little as 5 Gm. of the drug appeared to have cleared the pneumococcal infection.

SUMMARY AND COMMENT

Seven patients who had been diagnosed as having pulmonary tuberculosis were treated with sulfapyridine. Patient 2 had acute generalized miliary tuberculosis, which was proved at autopsy, and was the only patient who had a negative sputum. He was in a moribund condition when he arrived at the hospital. We do not feel that sulfapyridine affected his disease in any way nor do we believe that it contributed to his death. Patient 4 received the largest total amount of the drug, 108 Gm., and patient 7 received the smallest, 5 Gm.

Hematuria and pain and tenderness developed in case 5 in the region of the left kidney after 19 Gm. of the drug had been given. An intravenous pyelogram followed by cystoscopic examination revealed an obstruction in the upper portion of the left ureter near the kidney pelvis. With considerable difficulty a catheter was passed to the left kidney pelvis and the obstruction was relieved. It was thought that this obstruction was due to the formation of ureteral stone or impaction from the settling out in the kidney pelvis of acetylsulfapyridine crystals.

Nausea and vomiting were the two most common toxic manifestations in our series, the former occurring in five of the seven cases, the latter in three. In three cases it was necessary to withdraw the drug permanently because of these symptoms. In one case it was necessary to withdraw the drug because of hematuria and ureteral obstruction. Two patients in this series have died of their disease. Patient 6, after 103 Gm., was showing such rapid spread of her pulmonary tuberculosis that her left lung was collapsed, following which she improved somewhat.

CONCLUSIONS

Seven patients with active pulmonary tuberculosis, one with acute generalized miliary tuberculosis, were treated with sulfapyridine. The object of our study was to ascertain the immediate effects of the drug on the tuberculosis over a relatively short period of time. Under the conditions described, no evidence was obtained to indicate that sulfapyridine influenced the course of the tuberculosis in these cases.

THECA CELL TUMORS OF THE OVARY

CONRAD G. COLLINS, M.D.

GEORGE VARINO, M.D.

AND

JOHN C. WEED, M.D.

NEW ORLEANS

Solid ovarian tumors, especially those producing endocrine changes, have been the subject of much discussion and investigation both by the pathologist and by the gynecologist during the past few years. Robert Meyer's¹ work, reported in 1931, was probably the spark that first aroused interest in America. In this publication he described the dysgerminoma ovarii, the granulosa cell tumor and the arrhenoblastoma. Later numerous reports of these tumor types appeared in the literature at frequent intervals, as did also reports of Brenner cell tumors; Bland and Goldstein² reviewed the literature and collected sixty cases of the latter type of tumor in 1935. Loeffler and Priesel³ in 1932 recorded six cases of ovarian tumors, which they termed "fibroma theca cellulari xanthomatodes ovarii," and in 1934 the same authors⁴ reported four additional cases of this type. In the same year Melnick and Kanter⁵ reported two similar cases, the first to appear in the American literature, for which they adopted the

term "theca cell tumors of the ovary." Geist,⁶ in a series of papers, reported a large number of tumors which clinically simulated granulosa cell tumors of the ovary and pathologically resembled fibromas of the same organ. He proved by an extensive study of his cases, which embraced clinical, microscopic, chemical and biologic methods, that although theca cell tumors simulate granulosa cell tumors clinically and fibromas of the ovary microscopically they are a definitely clinical entity.

To date only twenty-four cases of theca cell tumors have been reported in the literature, and to this number we add two cases which have come under our observation during the past year.

HISTOGENESIS

The histogenesis of solid ovarian tumors has not been definitely established. One school, the disciples of Pflüger's theory, maintains that the granulosa cells and the theca interna cells of the ovary are derived from the gonadal epithelial covering. Fischel believes that the epithelial cells are derived from the mesenchyme of the ovary and that the germinal epithelium acts only as a nonfunctioning layer surrounding the ovary and contributes in no way to its structure. According to Robert Meyer,¹ granulosa cell tumors arise from mesenchymal embryologic rests ("granulosaballen"), in the hilus of the ovary, a view which is also supported by Walter Schiller.⁷ Recently Voigt⁸ reported a case of primary granulosa cell tumor of the retroperitoneum, and the fact that this primary tumor developed in a site far removed from functionless ovaries certainly lends strength to Fischel's theory. Geist⁹ is of the opinion that granulosa cell tumors and theca cell tumors arise from differentiated mesenchymal cells which are potentially capable of becoming either granulosa or theca cell in type. Novak¹⁰ is of the same opinion and for this reason opposes segregation of theca cell and granulosa cell tumors. Greenhill and Greenblatt¹¹ recently reported a case of combined theca and granulosa cell tumors and concluded that this case gives much weight to the theory that theca cell tumors and granulosa cell tumors originate in a common type cell of the ovarian mesenchyme, the "progranulosa cell."

Recent experimental production, by means of x-rays, of theca and granulosa cell tumors in the ovaries of mice, some of which showed definite lutein change, have

Fig. 1 (case 1).—Cut surface of theca cell tumor showing islands of yellow tissue separated by bands of fibrous tissue.

been carried on by Furth and Butterworth¹² and by Traut and Butterworth.¹³ Through these experiments, evidence is produced that, in experimental animals at least, granulosa cell tumors might arise from surviving adult granulosa cells. Certainly, although the exact manner of origin of theca cell tumors and of the closely related granulosa cell tumors is still a matter of conjecture, the preponderance of evidence is in favor of Fischel's theory of mesenchymal origin of the theca and granulosa cells.

PATHOLOGY

Theca cell tumors vary in size from a few centimeters in diameter to the size of a large grapefruit. On vaginal examination the consistency is that of a fibroma of the ovary or of a fibromyoma of the uterus. The same consistency is noted when the tumor is examined following removal. Externally the growth is slightly irregular in outline and varies in color from yellowish brown to yellowish red. On cut section the tumor is encapsulated and composed of many islands of yellow tissue separated by bands of connective tissue; occasionally small cystic areas may be noted throughout the tumor. Microscopically, theca cell tumors are made up of interlacing bands of spindle or epithelioid cells irregularly distributed and separated by strands of connective tissue containing hyaline plaques. The nuclei are oval and rod shaped with an occasional mitotic figure present. Fat stains show the presence of intracellular and extracellular lipid material, which, according to Geist, is doubly refractile and probably consists of cholesterol or cholesterol esters.

CLINICAL FEATURES

Theca cell tumors of the ovary are usually unilateral and are of the consistency of a fibroma of the ovary or fibromyoma of the uterus. They occur at any age, the oldest reported case being that of a woman aged 90 and the youngest that of a woman aged 18. All but three of the reported cases occurred at or past the

menopause. That theca cell tumors are biologically active is evidenced by the atypical bleeding found in the menopausal and postmenopausal cases and by the occurrence of endometrial hyperplasia in a large number of these cases. In younger women, periods of amenorrhea, preceded or followed by menorrhagia, is the usual his-

tory. Although only one case has been examined by hormone assay, the finding of a large amount of the estrogenic substance in this case and the frequency with which hyperplasia of the endometrium has been encountered in other cases of this type present sufficient evidence to indicate that usually the estrogenic substance is found in these cases in larger quantities than in normal ones.

REPORT OF CASES

CASE 1.—History.—A. M. C., a woman aged 24, admitted to Charity Hospital Nov. 27, 1937, complained chiefly of pain in the right side and amenorrhea. She stated that she had not menstruated since Jan. 13, 1937.

Fig. 3 (case 2).—Cut surface of tumor shown in figure 2. Note islands of tumor tissue separated by bands of connective tissue.

Prior to that time her menstrual periods had occurred approximately every twenty-eight days and had lasted for a period of three days. The menstrual cycle began when the patient was 10 years old. She had been married for ten years and had been pregnant once, resulting in a normal delivery nine years before. Her last menstrual period began Dec. 15, 1936, and continued until Jan. 13, 1937. For four months prior to admission she experienced pain in the right side and right lumbar region. There had been a slight leukorrheal discharge, and the patient had noticed a mass in the right side for three weeks. Other features of the history were irrelevant.

Examination.—On physical examination the blood pressure was 140 systolic, 80 diastolic. The breasts were flabby and a mass was felt in the right side of the abdomen. Otherwise, the general physical examination was negative.

On vaginal examination, the external genitalia and Skene's and Bartholin's glands were normal. A mild cystocele and rectocele were present. The cervix was slightly enlarged and soft with a moderate degree of infection. The size, shape, position and mobility of the uterus were normal. There was a mass in the right adnexa the size of a golf ball, not attached to the uterus, and of firm consistency.

Laboratory examination of the urine was negative. The Wassermann reaction was negative. The blood pressure was within normal limits. X-ray examination of the chest and of the sella turcica showed no evidence of pathologic changes. X-ray films of the kidney, ureter and bladder were negative. The blood count was well within normal limits. The basal metabolic rate was minus 5.

The preoperative diagnosis was chronic cervicitis and luteinized granulosa cell tumor of the ovary.

Operation.—This consisted of dilation and curettage and of laparotomy. On examination of the pelvis, the uterus was found to be normal in size, shape and mobility. The left adnexa were normal. On the right side a large, firm, yellow ovarian tumor approximately 5 cm. in diameter was found. It was freely movable and involved the whole of the ovary. Ascites was not present. A right oophorectomy was performed and the abdomen was closed in anatomic layers. The patient had a normal postoperative course and was discharged on the tenth postoperative day.

Pathologic Reports.—Gross: The tumor measured 5 cm. by 5 cm. and was yellowish red and firm. Cut section revealed the tumor to be made up of numerous islands of yellow tissue, separated by bands of connective tissue. On exposure to air the yellowish color deepened.

Microscopic: Uterine scrapings were examined microscopically. Section of the endometrium showed inactivity and hypoplasia of glandular elements. Slight secondary infection was noted. Section of the ovary showed the tumor to be made up of numerous bands of interlacing fibrous connective tissue separating masses of irregularly arranged spindle shaped cells. Fat stains showed the presence of lipoids in large amounts both intracellularly and extracellularly.

Follow-Up.—The patient menstruated five weeks after operation and has menstruated regularly ever since, menstrual periods occurring approximately every twenty-eight days and lasting from three to four days.

CASE 2.—History.—Mrs. L. B. aged 22, admitted to Touro Infirmary April 19, 1938, complained chiefly of amenorrhea. The patient missed her October 1937 period but menstruated at the end of November. She did not menstruate in December 1937 or January 1938 but did in February and March. All periods were normal when present. Menstrual periods began at the age of 12 years and occurred at from twenty-eight to thirty day intervals, lasting from four to five days. Severe dysmenorrhea was present on the first day of each period, but the flow was normal in amount and character. She had never missed a period before October 1937. She was married in July 1937 and had used contraceptives ever since and had never become pregnant. Prior to admission she had not menstruated for seven weeks. There were several attacks of pain in the

Fig. 4 (case 1).—Theca cell tumor under low power showing spindle shaped cells separated by bands of connective tissue and containing hyaline plaques.

lower right quadrant for two months, the pain radiating down into the pelvis. Otherwise the patient's history was irrelevant.

Examination.—The blood pressure was 120 systolic and 70 diastolic. The breasts were small, and aside from a suggestion of masculine distribution of the pubic hair there were no abnormalities noted.

Vaginal examination revealed a nulliparous outlet, intact perineum, no cystocele or urethrocele and no infection of Bartholin's or Skene's glands. The cervix was small. The uterus

was normal in size, shape and mobility. The left ovary was palpable but of normal size. The right ovary was enlarged to the size of a small grapefruit and very hard and firm.

The Wassermann reaction was negative. The urine was normal and a blood count was within normal limits.

The preoperative diagnosis was theca cell tumor of the right ovary.

An operation was performed April 21 with a subumbilical mid-line incision. Exploration of the pelvic cavity showed that the uterus was normal in size, shape, position and mobility. The right tube was normal but the right ovary was large, the size of a small grapefruit and freely movable. The tumor occupied the entire ovary, was freely movable, slightly irregular in outline and of yellowish red. The tumor was firm and there was

Fig. 5 (case 2).—Theca cell tumor under high power showing epithelioid cells.

no evidence of ascites. A right oophorectomy and appendectomy were performed. The abdomen was closed in anatomic layers.

Pathologic Report.—Gross: The tumor measured 10 by 12 cm. in diameter and occupied the entire ovary; it was slightly irregular in outline and of very firm consistency. The external coloring varied from yellowish red to yellowish brown. A few dilated blood vessels coursed over the surface of the ovary. On cut section the tumor was found to be solid and made up entirely of areas of yellow tissue separated by thin septums of connective tissue.

Microscopic: Section of the ovary showed that it was made up of bundles of elongated cells with nuclei that were oval and rod shaped, separated by small amounts of intracellular substance. An occasional mitotic figure was noted, although the cells were for the most part well differentiated. Histologically it was a supportive cell neoplasm. No epithelial elements were demonstrated. A fibroma was present.

A corrected pathologic report demonstrated a theca cell tumor of the ovary and chronic appendicitis. Fat cells showed presence of intracellular and extracellular lipoid material in large amounts.

Follow-Up.—The patient menstruated four weeks after operation and has menstruated at regular intervals ever since.

COMMENT

As a general rule, theca cell tumors occur at or past the menopause. Of the twenty-four cases reports of which have appeared in the literature, only three have

occurred in younger women (Loeffler and Priesel, one case; Geist, two cases). Both of our cases occurred in young women, and, in contrast to the menorrhagia at the menopausal age, both of our patients had a period of amenorrhea of varied duration. This is true also of the cases of theca cell tumors that appeared in younger women which were reported by Loeffler and Priesel and by Geist. The history of periods of menorrhagia followed by or preceded by periods of amenorrhea and accompanied by the clinical finding of a unilateral solid ovarian tumor should arouse suspicion as to the existence of a theca cell tumor, even in a young female. In the second case, although the first pathologic report was that of fibroma, we were so confident that such was not the case that we persuaded the pathologist to restudy the slides and make special fat stains of the tumor. This led to a corrected diagnosis of theca cell tumor. Undoubtedly a number of cases of theca cell tumors have been reported in the past as fibromas of the ovary. Correlation of the clinical history of abnormal bleeding and the luteinized appearance of the tumor should suggest the possibility of theca cell tumor, and extensive microscopic study should be made by the pathologist to determine its presence. Otherwise we are certain that the majority of these cases will be reported as fibromas. Unfortunately we failed to obtain any endometrium from our second case. The first case, however, showed an inactive endometrium with hypoplasia of the glandular elements. This finding we are unable to explain. The majority of theca cell tumors reported have shown definite hyperplasia.

In both cases unilateral oophorectomy was performed. The uterus, both tubes and the remaining ovary were allowed to remain in situ, as the tumors were grossly benign and only two of the reported cases have been malignant. Since removal of the tumors, normal menstrual cycles have been reestablished in both cases.

CONCLUSIONS

1. Theca cell tumors are a definite clinical entity and, though occurring most frequently at the menopause, may occur at any age.

2. From the reported cases and our two cases of theca cell tumors occurring in young women, it would seem that theca cell tumors may produce menorrhagia in younger women but that amenorrhea of varying periods is the rule. In women near the menopause, menorrhagia is the rule.

3. Unless fat stains and special studies are made of solid ovarian tumors, especially when associated with amenorrhea or menorrhagia, a number of theca cell tumors will continue to be erroneously diagnosed as fibromas.

1430 Tulane Avenue.

First Recorded Pandemic Plague.—The first recorded pandemic of plague according to Wu was that of Justinian in the sixth century, starting in Egypt in 542 A. D. and spreading to Constantinople. It lasted fifty to sixty years, and its victims are estimated at 100,000,000. The second plague pandemic, the "Black Death," took place in the fourteenth century in Europe and claimed 25,000,000 victims or about one fourth of the population. In Great Britain from half to two thirds of the people perished. The great plague epidemic of London, 1664-1666, is said to have killed 70,000 persons out of a total population of 450,000. Plague disappeared from England in about 1680, having been almost continuously present for nearly 140 years, with five epidemics.—Hermes, William B.: Medical Entomology, New York, Macmillan Company, 1939.

Clinical Notes, Suggestions and New Instruments

SULFANILAMIDE IN STAPHYLOCOCCIC SEPTICEMIA TWO CASES WITH RECOVERY

WILLIAM A. THORNHILL JR., M.D.; HOWARD A. SWART, M.D.,
AND CLIFTON REEL, M.D., CHARLESTON, W. VA.

Staphylococcic septicemia has long been considered as almost invariably fatal, and the finding of staphylococci in the blood stream of a patient with septicemia has led to the rendition of many a hopeless prognosis.

The recent introduction of sulfanilamide, and its use in infections of all types, has been of interest to all medical practitioners.

We have found one report of staphylococcic septicemia successfully treated with sulfanilamide. Morris¹ reports the use of antitoxin, transfusions and sulfanilamide for treating a white man aged 37 whose blood cultures showed *Staphylococcus albus* on four occasions.

REPORT OF CASES

CASE 1.—A white man, aged 31, was admitted to the Charleston General Hospital, Aug. 17, 1938, with the history of having jabbed the end of a pick into his knee nine days before admission while working as a coal miner. The patient noticed that shortly afterward the knee became painful and swollen. His doctor gave him tablets of mercury bichloride to dissolve in water for bathing the knee. In spite of this treatment the knee became worse.

Examination on admission revealed that the knee was swollen and tender. There was a small, unhealed puncture wound, which showed some infection, over the patella. The thigh was also swollen and tender. X-ray examination of the knee was negative. The patient's temperature on admission was 98 F. This rose to 102 F. at 4 p. m. and to 103.8 F. at 8 p. m. Urinalysis August 17 showed albumin (1 plus), no sugar, casts (1 plus), an occasional red blood cell, pus (1 plus) and mucus (1 plus). Treatment by means of continuous warm moist dressings to the knee and thigh was started.

August 18 his temperature was 104.4 at 8 p. m. Sulfanilamide 20 grains (1.3 Gm.) every three hours was started. This was accompanied by sodium bicarbonate 15 grains (1 Gm.) twice a day.

August 19 the swelling of the knee had receded. The patient was coughing and complaining of inability to breathe. A roentgenogram of the chest was negative. His temperature on this day was 102.5 F. at midnight.

August 20 a blood culture was reported as showing 5 colonies per cubic centimeter of an organism, probably *Staphylococcus aureus*. The hemoglobin, which had been 70 per cent August 19, had dropped to 59 per cent. Widal and undulant fever tests were reported negative, as was the blood Kline test. The sulfanilamide concentration in the blood on this date was 1.5 mg. per hundred cubic centimeters.

The patient was very ill at this time, being delirious and noncooperative. His condition seemed precarious. A transfusion of 500 cc. of blood was given August 20. On this day his temperature rose to 105.4 F. The pulse during this time was running between 120 and 140. The abdomen was somewhat distended and the patient perspired freely.

August 21 the temperature dropped to 100.4 F. at 8 a. m. However, it rose again to 103.4 F. at 8 p. m. On this day the hemoglobin was 70 per cent, erythrocytes 4,600,000 and leukocytes 16,000. The sulfanilamide concentration in the blood had risen to 3.5 mg.

August 22 cellulitis on the lateral side of the thigh was definitely present. The temperature ranged from 101.4 F. at 4 a. m. to 104.4 at 8 p. m. The patient did not respond to questions. Roentgen therapy was given, also a transfusion of 250 cc. of blood.

August 23 a second culture showed *Staphylococcus aureus* with not as many colonies as in the first culture. The blood sulfanilamide concentration at this time was 5 milligrams per hundred cubic centimeters.

The patient was given sulfanilamide during this time and had transfusions of 250 cc. of blood every other day. His temperature varied from 102 F. to 103 F. and on August 29 fluctuation was detected on the lateral side of the left thigh. The same day, under local anesthesia, an incision was made and 300 cc. of thin yellow pus was evacuated. Warm moist dressings were again started.

Following this procedure the leg drained thin yellow pus in increasingly smaller amounts and the temperature slowly receded. Blood sulfanilamide determinations were reported as 10.5 mg. August 26, August 29 and September 1.

A third blood culture was reported August 26 as showing *Staphylococcus aureus haemolyticus*, and culture from the pus of the abscess showed *Staphylococcus aureus*, slightly hemolytic. September 9 blood culture showed only one colony of *Staphylococcus aureus* after four days' growth. The blood sulfanilamide ranged from 10.5 mg. September 1 to 6.8 mg. September 2.

The patient made a slow but continuous improvement. September 12 there was practically no drainage from the leg, and warm moist dressings and sulfanilamide were discontinued. However, because of reports that improvement following the use of the drug was not maintained after its withdrawal, the administration of sulfanilamide was started again.

September 12 blood culture was reported as follows: "Plates sterile, slight growth of staphylococcus in broth." September 20 blood culture was sterile after seven days and on September 26 a similar report was made. October 3 the culture was sterile after eight days.

September 20 the sulfanilamide was again stopped. While the patient felt very much better, his temperature never dropped below 100 F. for any length of time and his leg still drained pus. He complained also of pain in his left shoulder, and a slightly tender swelling eventually appeared in the left axillary space.

He had received 5,450 cc. of blood in thirteen transfusions over a period of thirty-nine days. His hemoglobin rose to 72 per cent October 6.

A roentgenogram of the femur October 5 showed subacute osteomyelitis, distal two thirds, shaft of femur, with irregular bone absorption and slight periosteal thickening. The process involved the knee joint.

It was considered inadvisable for the patient to go home because of the continued elevation of temperature and axillary swelling, but he became very anxious to leave and was discharged October 7, fifty-one days after admission. He returned to the hospital October 28, twenty-one days after discharge, complaining of pain and swelling under the left arm. He was found to have marked axillary adenitis and cellulitis of the shoulder region. Roentgenograms were negative. At this time the leg wound was healed but there was little motion in the knee.

His temperature on readmission was 102.6 F. by mouth at 4 p. m. His blood count showed 52 per cent hemoglobin, 2,800,000 erythrocytes and 21,500 leukocytes, of which 94 per cent were neutrophils. Urinalysis was essentially negative.

Treatment was instituted by means of warm moist dressings to the region of the shoulder, sulfanilamide 5 grains (0.3 Gm.) every hour and blood transfusions.

An axillary abscess formed, and on November 12, fifteen days after the second admission, it was incised under local anesthesia and 200 cc. of thin yellow pus evacuated.

Blood cultures on this visit were sterile after forty-eight hours and after seven days. Culture of the pus from the abscess showed *Staphylococcus aureus*, slightly hemolytic.

Sulfanilamide was continued until November 23. The blood sulfanilamide rose to 11.8 mg. at this time. Drainage from the wound gradually subsided, leaving the shoulder joint very stiff.

He received three blood transfusions, 1,150 cc. of blood in all, at this visit. His hemoglobin, which was 52 per cent October 29, dropped to 36 per cent November 7 but rose again to 62 per cent November 17.

1. Morris, John F.: *Staphylococcus Septicemia*, West Virginia M. J., 35: 186-187 (April) 1939.

He was again dismissed from the hospital December 9, at which time the axillary wound was almost completely healed. The shoulder was very stiff. There was little motion in the left knee and some weakness of the external lateral ligament of this knee.

Because of the bad roads and inaccessibility of his home, he was not seen again until March 9, 1939, three months after leaving the hospital. At this time he had complete and painless motion in the left shoulder. He had only 20 degrees flexion of the left knee, however. The wound of the leg was healed and he walked with a cane.

He returned to the hospital May 22, at which time it was found that there was drainage again from the sinuses on the lateral surface of the thigh. The knee was stiff in a position of 165 degrees extension. He was again treated with warm moist dressings and traction and when last seen there was still some drainage of pus from the thigh.

CASE 2.—J. B., a white boy aged 15 years, was first seen by F. C. R. on the third day of his illness complaining of pain in the left upper jaw, for which he had consulted his dentist the preceding day. He was referred as having no dental lesion. His family and past histories were noncontributory except for tonsillectomy in 1937.

The patient was apparently healthy and cooperative. The left side of the face was generally swollen and red, including both eyelids. There was injection of the conjunctivae and limitation of the excursion of the eyeball. The infra-orbital area medial to the foramen was tense, and palpation yielded a sensation of fluctuation. The left side of the nose was blocked by edematous, reddened mucous membrane and seropurulent drainage. The antrum was dark on transillumination. There was some pharyngeal congestion and slight cervical adenopathy. Antral irrigation produced a few cubic centimeters of fine granular pus.

The patient was admitted to an eye, ear, nose and throat hospital the following day because of an increase in his cellulitis and a rise of temperature to 103.2 F. His blood count was reported to show 70 per cent hemoglobin, 3,900,000 erythrocytes and 14,600 leukocytes, with 86 per cent polymorphonuclear forms, 11 of which were immature. Nasal smear and cultures revealed both a streptococcus and a staphylococcus. The urine showed albumin, pus and an occasional red blood cell and granular cast.

On the fifth day of his disease the infra-orbital abscess was incised and pus evacuated. The fever level remained about 104 F. By the eighth day an abscess which had formed in the left tonsillar fossa was incised and drained profusely. The same day he developed proptosis of the right eye with marked injection, and small hyperemic areas over the left anterior superior iliac spine and right heel with scattered petechiae over the extremities. His leukocytic count was 18,400 with essentially the same differential picture. There was less albumin and pus in the urinary specimen. He became semicomatose, but his response to intravenous fluids was gratifying.

At this point he was seen by one of us (W. A. T.), and transferred by ambulance to a general hospital with a clinical diagnosis of septicemia and a cavernous sinus thrombosis, secondary to a spontaneous left infra-orbital abscess. Blood culture was taken, sulfanilamide therapy instituted, and transfusion performed. The blood culture showed 50 colonies per cubic centimeter of hemolytic *Staphylococcus aureus*. The leukocyte count was 20,400 per cubic millimeter. Eighty-six per cent of these cells were polymorphonuclears. There were 4,000,000 erythrocytes with 68 per cent hemoglobin. His blood sulfanilamide level was maintained between 4.0 and 7.65 for the first sixteen days of his second hospitalization with constant dosage. He was then given a respite of one week and returned to a steady dosage for nineteen more days. He received during the course of his illness 865 grains (56 Gm.) of sulfanilamide. Transfusions of 250 cc. of citrated blood were given on fourteen occasions between the fifteenth and fiftieth days of his illness. Bilateral proptosis prompted a diagnosis of bilateral cavernous sinus thrombosis and he had a paralysis of the left fourth nerve,

which did not clear up until some three months after his acute stage. There was also transient paralysis of his seventh and ninth nerves on the left. Ten days after his hospital transfer thick yellow pus was aspirated again from his infra-orbital abscess, and incision and drainage were performed. An acute bilateral otitis media developed but subsided without drainage.

He was discharged on the fiftieth day of his illness but continued to have a low grade fever at home for some weeks. He also had a subcutaneous infection on his right forearm, which persisted unchanged for about two weeks in spite of roentgen treatment and eventually had to be opened during his convalescence in Florida. A roentgenogram of the arm indicated periostitis. After incision and bone scraping, drainage persisted for one month. He has at this date still some periostitis and drainage from the forearm, though he otherwise is quite well.

COMMENT

It has been thought desirable to report these cases because of the failures in treating staphylococcal septicemia and because of the widespread interest in the use of sulfanilamide. How much of the credit for the cure must be given to the blood transfusions and roentgen treatment in the one case is difficult to decide. The transfusions bolstered up the patient's hemoglobin, which was attacked by both the infectious process and the sulfanilamide. The roentgen therapy undoubtedly helped to localize the abscess in the leg.

The use of so many therapeutic agents in the treatment of this disease is evidence that no one of them is effective in every case. Another point brought out by a study of the literature is that the number of cases of the disease is comparatively small and few men become proficient in its treatment. Sulfanilamide is much more easily procurable than either antitoxin or bacteriophage, and if further successes follow its use in this disease it would seem to be the method of choice.

CONCLUSION

Two patients with *Staphylococcus aureus* haemolyticus septicemia with formation of localized abscesses recovered following the use of sulfanilamide, blood transfusions and drainage of the abscesses.

SULFAPYRIDINE IN THE TREATMENT OF STAPHYLOCOCCUS AUREUS BACTEREMIA

SAMUEL L. GOLDBERG, M.D., and ALLAN SACHS, M.D.
CHICAGO

Much interest has been aroused by the advent of sulfapyridine. Although its use has been almost limited to the treatment of pneumonic processes, its efficacy in other conditions has been briefly reported.

Instances of the use of the drug in staphylococcal septicemia or bacteremia of necessity are few and brief. Fenton and Hodgkiss¹ reported its use in a case with an atypical clinical picture. A single culture of the blood revealed *Staphylococcus aureus*. The only significant finding was x-ray evidence of pleural thickening. The temperature dropped markedly twenty-four hours after administration of the drug. O'Brien and McCarthy² reported staphylococcal bacteremia following furunculosis, with a dramatic drop in temperature and sterile blood culture following therapy with sulfapyridine. Maxwell's³ patient had staphylococcal bacteremia coincidental to pneumonia. Staphylococci were recovered from two cultures of the blood. The temperature dropped to normal in forty-eight hours and culture of the blood became sterile seven days later. Long⁴ mentions rapid sterilization of the blood after the institution

From the Surgical Service of Michael Reese Hospital.
The Department of Bacteriology, Dr. Katharine M. Howell, director, cooperated in doing the bacteriologic work.

of sulfapyridine therapy in three of five patients ill with staphylococcic bacteremia. This is what he expected as a result of his experimental work with animals.

REPORT OF CASES

To these brief reports can be added our two cases:

CASE 1.—M. K., a white girl aged 28 months, entered Sarah Morris Hospital Feb. 3, 1939, with complaints of swelling and

leg, which was symmetrical from the knee to the ankle with tightly stretched skin. The anterior tibial surface was red, warm and indurated. A diagnosis of osteomyelitis with subperiosteal abscess was made.

The patient was operated on under ethylene anesthesia. A subperiosteal collection of pus was found at the upper portion of the tibia. Drill holes were made, and pus was obtained from the marrow cavity. A window of bone was cut out and

Chart 1.—Temperature, blood counts, blood culture and treatment in case 1.

pain of the left lower leg. There was a history of previous furunculosis with a large carbuncle on the buttock. One week before admission this carbuncle had been accidentally injured, following which there was purulent drainage. During the next

petrolatum packing inserted. Cultures of the pus obtained showed hemolytic *Staphylococcus aureus*.

After operation, the course was marked with daily temperature spikes from 102 to 104 F. rectally, as shown in chart 1.

Blood cultures revealed hemolytic *Staphylococcus aureus*. Multiple small transfusions of citrated blood were given and large doses of sulfanilamide were started. Although the temperature dropped slowly, the patient continued to be very toxic and the blood cultures continued positive for *Staphylococcus aureus*.

Since the sulfanilamide over a long period did not sterilize the blood stream, it was discontinued. In an effort to accomplish this sterilization, treatment with sulfapyridine was begun. This 30 pound (13.6 Kg.) child was given 45 grains (3 Gm.) of sulfapyridine daily in six divided doses. On the fifth day blood culture was negative. The same dosage was continued for six more days when the temperature, which had been dropping, reached normal and the toxicity disappeared. The dose was then reduced to 30 grains (2 Gm.) daily for five days and then stopped. There was never any vomiting. The general condition improved rapidly in spite of an upper respiratory infection and fever for several days. During the period of sulfapyridine therapy

all other medications were discontinued except for hot wet dressings locally. Because of the anemia, a blood transfusion was given at the end of the course of sulfapyridine.

CASE 2.—E. M., a white boy aged 11 years, who entered Sarah Morris Hospital May 5, 1939, had a severe chill one week previously, followed by a rise in temperature. The next day there was pain, swelling and redness of the anterior aspect

Chart 2.—Temperature, blood counts, blood culture and treatment in case 2.

three days the patient had a series of chills with high temperature and anorexia. Following this she developed pain, and then swelling of the left leg from the knee to the ankle. The history is otherwise irrelevant.

Physical examination on admission revealed a rectal temperature of 104.2 F. There were no abnormalities other than a healing infection of the buttock and the swelling of the left

of the right lower leg. These became more pronounced daily, with a gradual rise in the rectal temperature to 104 F. There was no history of recent trauma, upper respiratory infection or furunculosis.

Physical examination revealed a rectal temperature of 103.6 F. The child was sick and toxic. Significant abnormalities were limited to the right lower leg. It was tense with swelling, red and hot. There was marked tenderness, which seemed superficial. Roentgenologic examination revealed no bone involvement. Cellulitis of the leg was the tentative diagnosis.

Massive hot wet dressings were applied to the local lesion. One hundred grains (6.5 Gm.) of sulfanilamide (1 grain per pound of body weight) was given in the first twenty-four hour period. The next day (May 6) fluctuation was evident and the localized abscess was incised. Eight ounces (235 cc.) of thick pus was evacuated. Culture of this pus revealed *Staphylococcus aureus*. The next day (May 7) there was a drop in the rectal temperature to 102.2 F. (chart 2) but the boy looked very sick. Blood drawn for culture May 7 and again May 8 revealed *Staphylococcus aureus* bacteremia.

On the afternoon of May 8 sulfapyridine therapy was begun. A total of 270 grains (18 Gm.) was given by mouth in nine divided doses the first thirty-six hours, after which the daily dose was reduced to 135 grains (9 Gm.).

May 9 the boy complained of pain in his right elbow. Examination revealed swelling, redness and tenderness. Hot moist dressings were applied. The local condition improved and seventy-two hours later all the signs of inflammation had completely subsided.

May 12, the fourth day following institution of sulfapyridine therapy, blood drawn for culture was sterile. There was a decided drop in temperature to 100.8 F., with marked improvement in the general condition. Repeated blood cultures May 13 and 15 remained sterile. May 14 the dose of sulfapyridine was reduced to 90 grains (6 Gm.) daily for the next three days.

The temperature dropped to normal May 15 and remained so until May 21, when it rose to 101 F. Roentgenologic examination of the leg and elbow at this time revealed osteomyelitis of the tibia and ulna. Sulfapyridine was again given in daily doses of 90 grains for three days, when the temperature again became normal. The leg improved during this period, there was less drainage, and the arm showed no recurrence of any signs of inflammation.

COMMENT

The effect of sulfapyridine on the local lesion is something regarding which little is known. The lesion of the ulna in case 2 interested us greatly. Signs of inflammation appeared over night and disappeared completely within three days, leaving no residue of either subjective or objective symptoms, and yet twelve days later there was definite roentgenologic evidence of bone destruction, which is progressing slowly and will probably require drainage. This phenomenon may prove a very valuable aid in the treatment of acute osteomyelitis, especially as the recent trend seems to be toward conservative management. Whether sulfapyridine will be of any value in reducing the duration of osteomyelitis is as yet an open question.

We realize the pitfalls of reporting only two instances of sterilization of the blood stream in *Staphylococcus aureus* bacteremia and claiming effectiveness for any therapeutic agent. Unquestionably the blood stream is sterilized by normal body defense mechanisms more often than we realize.⁵ Instances of such sterilization after the use of staphylococcus antitoxins are being reported in the literature more frequently. However, the change in the clinical pictures in these cases was striking enough to lead us to believe that sulfapyridine was instrumental in sterilizing the blood stream. The disease is one which has a high mortality, and any agent which might have any beneficial effect is worthy of further investigation, especially since the meager investigative work done so far would point to some specific action of this drug against the staphylococcus. Proper evaluation of the effectiveness of the drug can be made only on a large group of cases.

TREATMENT OF FRIEDLÄNDER'S SEPTICEMIA BY SULFAPYRIDINE WITH RECOVERY

KARL A. MEYER, M.D., AND LEO AMTMAN, M.D., CHICAGO

Septicemia resulting from *Bacillus mucosus capsulatus* (Friedländer's bacillus) is rare. It is in the French literature that one finds the most frequent reports. Colombe¹ in 1917 collected sixty cases from the world's literature, of which twenty-five were diagnosed during life by a positive blood culture. Causade, Joltrain and Surmont² collected fifteen new cases which occurred from 1917 to 1924 and reported their own case. Since then a case has been reported by Creyx³ and another by Lereboullet and Pierrot⁴ in which recovery occurred. In 1924 Lereboullet and Denoyelle⁵ reported two cases in children who recovered. In 1928 Mason and Beattie⁶ reported their own fatal case, in which the portal of entry of the organism was not determined. They reviewed the literature and made mention of the fact that the "occurrence of septicemia from infection with *Bacillus mucosus capsulatus* is not generally recognized in Canada." Apparently up to 1927 there are only a few cases of Friedländer's septicemia in which recovery has occurred. In 1934 Baehr, Schwartzman and Greenspan⁷ cited sixteen cases of *B. Friedländer* bacteremia, with recovery in four. Three of the patients who recovered had infections of the kidney and urinary passages. The authors point out that blood invasions from this source are often transient and that in two of the cases the organism was recovered from the blood stream only on the day following a urethral or ureteral chill. The other patient who recovered had an infection of the biliary passages. Kolmer⁸ lists *Bacillus mucosus capsulatus* as an organism producing one of the rarer septicemias. He totals observations in 282 cases of septicemia. He states that case reports dealing with blood stream infections due to *Bacillus mucosus capsulatus* are uncommon and that reports showing complete recovery are rare. Since 1934 approximately twelve cases of this type of septicemia have been reported in the literature.⁹

REPORT OF CASE

L. N., a man aged 55, was first seen at home May 6, 1939, with a history of a sudden onset of septic temperature of eleven days' duration. There were no symptoms which would point to acute infection of the upper respiratory tract. For one week he had a violent chill on the average of once every day, usually in the evening but not at the same time. The chill, which lasted from twenty to forty-five minutes, was always followed by a fever of 103-104 F. and profuse sweats. When first seen at home, the patient appeared toxic with a temperature of 103 and pulse of 100. The only positive manifestations were diffuse dry rales and an occasional moist rale throughout the chest, especially in the lower lobes, and slight tenderness in the right upper quadrant of the abdomen. The spleen was enlarged on percussion. The condition in the chest persisted even after recovery, and this was interpreted as a chronic bronchitis. There was no expectoration. It was observed that the temperature between the paroxysms was almost normal. Smears were made for malaria, but no parasites were found. The therapeutic test with quinine was negative. X-ray examination of the sinuses and chest were negative.

May 8, at the patient's home, blood was drawn for routine agglutination tests and beef broth was inoculated for culture. The laboratories of the Chicago Board of Health reported

Smear from blood culture; Gram stain.

Bacillus mucosus capsulatus isolated from the broth culture and also from the blood clot in the specimen submitted for the agglutination tests. Smears showed a gram-negative short thick bacillus with a definite capsule. It fermented all the sugars except lactose. A mouse inoculated subcutaneously with the organism was found dead the next morning. A positive culture was obtained from the heart's blood.

The patient was removed to the hospital May 10. Blood culture done on the same day showed the same organism. A third culture May 12 after treatment was started showed only a few colonies of the same organism after ten days' incubation.

At 9 p. m. May 11, shortly after a severe chill, sulfapyridine was started with 30 grains (2 Gm.), followed by 15 grains (1 Gm.) every four hours, day and night. There were no more chills. After forty-eight hours the temperature remained normal with the exception of a single rise to 102 on the fifth day following institution of treatment. The drug was therefore continued until 9 a. m. May 22. Complete blood counts and urine examinations were done daily. There were no untoward effects observed from the drug. The patient has remained well to the date of this writing.

COMMENT

With no definite specific treatment for Friedländer's septicemia outlined in the literature, we felt that on the basis of

the recent experimental work on mice infected with pneumococci and treated with sulfapyridine the clinical use of this drug was justified in our case. Whitby¹⁰ states that in pneumococcal infections the drug acts by bringing about degenerative changes in the capsular material of the pneumococcus. Fleming¹¹ and Long¹² unable to confirm this, did note that the multiplication of susceptible organisms is hampered both in vivo and in vitro following the administration of sulfapyridine to mice or culture mediums. Long therefore suggests that careful therapeutic trials of the effects of sulfapyridine in Friedländer's bacillary infections seem warranted. This we did with presumptive success. We therefore report this as a proved case of *Bacillus mucosus capsulatus* (Friedländer's) septicemia with portal of entry unknown, which was treated with sulfapyridine and ended in recovery.

A METHOD OF TIMING HEART MURMURS

BERNARD FARFEL, M.D., HOUSTON, TEXAS

It seems that many physicians have little difficulty in learning to recognize normal heart sounds or in detecting the presence of a cardiac murmur but often their determination of the time of a murmur in the heart cycle is faulty. Cabot¹ states that the commonest of all errors in diagnosis of diseases of the heart is the misinterpretation of systole for diastole.

In routine examinations, many physicians rely on the ear alone, calling on palpation or observation of the apex, carotid or radial impulse when in doubt. That present clinical procedure is not entirely satisfactory is borne out by the frequent errors every physician sees or makes himself. Mackenzie² writes from his experience with recognized internists that many doctors never acquire the ability to time murmurs. Warfield, writing in Tice,³ points out the possibility of mistaking a seesaw murmur in mitral stenosis with regurgitation for a prolonged systolic murmur. It would be presumptuous to dwell on the importance of proper timing of murmurs for physical diagnosis.

The method I am about to describe requires none of the intricate types of apparatus that have been devised. It requires nothing that the physician does not ordinarily have at the bedside. My own experience with palpation coincident with auscultation has been one of difficulty in correlating the two sensations so as accurately to time the murmurs I hear. I felt that I would better be able to time the murmurs heard were I able to employ vision in conjunction with hearing, and I particularly sought some method which could be used in all cases. I have utilized the method to be described in numerous instances and have found it useful. I taught the method to several of my associates, with gratifying results.

Briefly, the following technic is employed: After I have taken the patient's blood pressure, I leave the cuff in place and set the mercury column at about midway between the systolic and diastolic blood pressure readings. This is done so as to obtain good excursions of the column with each beat. If one listens to the normal heart, it will be found that the upward excursion of the mercury column is coincident with the second heart sound. In this way one has already established a point at which systole ends. Cabot¹ teaches that the mistaking of systole for diastole would not occur if the physician were sure just when systole takes place. Knowing that the second heart sound and the impulse given to the mercury are coincidental, one should note whether the murmur in question immediately precedes this phenomenon, as would be true of a systolic murmur, or follows it, which would be the case with a diastolic murmur.

10. Whitby, Lionel: *Lancet* 2: 1095 (Nov. 12) 1938.

11. Fleming, Alexander: *Lancet* 2: 74 (July 9), 564 (Sept. 3) 1932.

12. Long, Perrin H.: *Sulfapyridine*, *J. A. M. A.* 112: 535 (Feb. 19) 1939.

1. Cabot, R. C.: *Physical Diagnosis*, Baltimore, William Wood & Co., 1931.

2. Mackenzie, Sir James: *Diseases of the Heart*, Edinburgh, Oxford University Press, 1925.

3. Tice, Frederick: *Practice of Medicine*, Hagerstown, Md., W. F. Prior Company, vol. 6, 1921.

That the second sound is dependent on aortic tension is pointed out by Howell,⁴ who quotes Williams' work on animals in which he shows that the second sound disappeared as an animal bled to death and the heart failed to throw out a sufficient supply of blood to maintain aortic tension. That the sudden thrust upward of the mercury should occur at the moment when the second sound takes place may be at least partially explained physiologically. Best and Taylor⁵ describe the rebound of the distended aortic wall at the close of systole, causing the aortic valves to close and forcing the blood along to the periphery as well.

It will also be observed, in using the method described, that the period during which the mercury falls slightly, just prior to the sudden rise, will usually coincide fairly well with the interval between the first and second sounds, namely systole. The technic given offers another means of timing murmurs. This communication is forwarded in the hope that a method that has proved useful to many of my associates and myself may be of some aid to others.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary.

RAVOX HEARING AID ACCEPTABLE

Manufacturer: Zenith Radio Corporation, 6001 Dickens Avenue, Chicago.

Description.—The Ravox Hearing Aid is supplied with power through a cord which connects to a nominal 110 volt, 60 cycle, alternating current electric light receptacle. On measurement it was found that the power consumption was 20 watts. The Ravox unit is housed in a formed sheet metal case of somewhat irregular shape but attractive design. The weight of the unit is 5½ pounds and the overall dimensions are approximately 4½ by 7 by 9 inches. A crystal type watch case receiver with head band plugs into a pair of phone jacks at the rear of the device. The microphone operates on the condenser principle and is suspended by means of shock absorbing coil springs directly behind a cloth covered grill located in the front face of the unit. The amplifier has three tubes of standard make.

The amplifier is provided with a combination shut-off switch and tone control located at the rear of the housing and a volume control knob located at the side.

Performance Tests.—Both single frequency response tests and speech tests (articulation and intelligibility) were made. For the single frequency tests the Ravox unit was suspended by its handle within a chamber which is substantially free from standing waves and excited by pure tones produced by a loud speaker unit and oscillator. The measured amplifications obtained with the volume control full on and with the tone control set for maximum high frequency gain are shown on the accompanying graph. Corresponding amplification determinations were made with the tone control set for minimum high frequency response, and it was found

Ravox Hearing Aid.

that above 2,000 cycles the amplification was reduced on the average by approximately 15 decibels, whereas below 1,000 cycles the gain was substantially unaltered. By direct listening it was observed that for each test frequency the sound output was quite pure and substantially free from harmonics or subharmonics, but there was present a hissing or rushing noise which interfered with the test tone when the output intensity fell to about the input intensity.

The performance of the Ravox hearing aid in transmitting speech sounds and sentences was very good. Thus with the

instrument adjusted for maximum high frequency response and placed in a small room having good acoustic properties, with observers having normal hearing in another room listening to the output, it was found that it was necessary to reduce the amplification approximately 45 decibels to produce a loudness in the Ravox receiver judged to be equal to loudness of speech when directly listened to. Under these circumstances the

Measured amplifications obtained with volume control full on and with tone control set for maximum high frequency gain.

inherent rushing sound previously mentioned was not objectionable and it was found that consonant-vowel-consonant syllables were transmitted over the Ravox with an almost perfect score. In fact no substantial difference in score was obtained when one was listening alternately to the sounds directly and over the Ravox link. Ordinary speech was likewise transmitted very efficiently. Hence it is concluded that the significant speech frequencies are transmitted by the Ravox hearing aid without admixture of disturbing sounds and amplification of approximately 45 decibels.

In view of the foregoing report, the Council on Physical Therapy voted to include the Ravox Hearing Aid in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

ASCORBIC ACID (See New and Nonofficial Remedies, 1939, p. 499).

Ascorbic Acid-Squibb.—A brand of ascorbic acid-N. N. R.

Manufactured by E. R. Squibb & Sons, New York City. No U. S. patent or trademark.

Tablets Ascorbic Acid-Squibb, 25 mg.: Each tablet is equivalent to 500 international units of vitamin C.

Tablets Ascorbic Acid-Squibb, 50 mg.: Each tablet is equivalent to 1,000 international units of vitamin C.

SULFAPYRIDINE-LEDERLE (See THE JOURNAL, June 24, 1939, p. 2603).

The following dosage form has been accepted:

Capsules Sulfapyridine-Lederle, 0.25 Gm.

COD LIVER OIL (See New and Nonofficial Remedies, 1939, p. 506).

I. V. C. Cod Liver Oil.—It has a vitamin A potency of not less than 2,250 units (U. S. P.) per gram and a vitamin D potency of not less than 260 units (U. S. P.) per gram.

Dosage.—For adults, 8 cc. (2 fluidrachms) daily; for children, 4 cc. (60 minims) daily.

Prepared by the International Vitamin Corporation, New York. No U. S. patent or trademark.

I. V. C. cod liver oil complies with the U. S. P. standards for cod liver oil. In addition it is required to have a vitamin A potency of not less than 2,250 units per gram and a vitamin D potency of not less than 260 units per gram.

SATURDAY, OCTOBER 28, 1939

EFFECTS OF AIRPLANE NOISE ON AVIATORS

Experiments have shown that prolonged stimulation of the ear by intense sound causes cochlear degeneration resulting in deafness. Bauer¹ in 1926 said that the constant noise of high powered airplane motors causes diminution in hearing. At first this deafness gradually wears off after a few hours, but constant flying without protection for the ears leads to permanent impairment of hearing. Kawata² subjected guinea pigs to noise for a month and on microscopic examination found complete degeneration of the organ of Corti at the point of transition from the basal turn to the second coil of the cochlea.

Recently British investigators Dickson, Ewing and Littler³ said that noise produced by certain types of multi-engined aircraft has been measured and found to reach loudness levels which are injurious to human ears. The loudness levels produced by various types of aircraft have been measured and have shown intensities of from 110 to 135 phons. Tests carried out on members of the Royal Air Force even after a few hundred hours of regular flying without helmets in enclosed cock pits showed a persistent loss of hearing for high tones. The observations included a complete aural examination in addition to audiometric tests. The subjects themselves were not always aware that their auditory acuity was impaired. This form of auditory defect probably is progressive in character as long as the patient continues to fly or to tune noisy aircraft. As the intensity and duration of the fatiguing sound was increased, all subjects showed a succession of phenomena. First there is an intensity value at C³, about 100 decibels above the threshold of audibility, exposure to which for as little as two minutes leads to aural fatigue involving subsequent depression of response.

Prolongation of the fatiguing sound beyond this point or further increase in its intensity causes greater immediate loss of sensitivity and slower recovery, until temporary deafness becomes chronic; still further increase in intensity brings about cochlear degeneration. The greatest hearing losses recorded in audiometric tests by the British investigators of patients suffering from traumatic deafness are almost always found in the frequency of C⁵.

Noise in connection with flying arises from three sources, the engine exhaust, the propeller and the wind (slip stream). Tests were made to determine the amount of protection of hearing provided by the standard pattern of flying helmet and other ear protectors and also to determine what protection can be afforded by simple ways of blocking the ear or packing the meatus. They learned that packing the meatus with absorbent cotton smeared with petrolatum was a quick, safe and efficient method. Audiograms of aviators using a helmet of the high altitude type with the ear phones attached showed no loss for high tones. The effect of noise on the ear seems to depend to some extent on the relative position of the aviators in the airplane. If the aviators sit well forward and in front of the engines, the effect is considerably less severe than if they sit below or between the engines. Investigation is being continued in the hope of finding still more effective methods of protecting the ears of aviators.

CARDIAC NEUROSIS

Cardiac neurosis is especially baffling in the patient in whom it is associated with organic heart disease. In a recent study of this problem, Schnur¹ has suggested a procedure which may prove to be valuable in the differentiation of the symptoms and signs of the neurosis from those of the organic disease. The chief precipitating cause of cardiac neurosis in a person suffering from heart disease, he points out, is professional exaggeration of the severity of the process. Pain is more frequently a presenting symptom in cardiac neurosis than in organic heart disease, except in coronary thrombosis. Among other symptoms more common in neurosis are weakness, sighing respiration, insomnia, ringing or pounding in the ears, and faintness, dizziness, nervousness, irritability and flushes. Deep tenderness in the inframammary area in his group of patients was elicited in only 5 per cent of patients having organic heart disease, as contrasted with 80 per cent of those suffering from neurosis alone. Similarly, superficial hyperalgesia was demonstrated in less than 2 per cent of those with organic disease, whereas the incidence in cardiac neurosis was 68 per cent. This frequent hyperalgesia suggested the intradermal injection of procaine hydrochloride into the affected area. Immediate disappearance of hyperalgesia, tenderness

1. Schnur, Sidney: *Cardiac Neurosis Associated with Organic Heart Disease*, Am. Heart J. 18: 153 (Aug.) 1939.

and pain resulted; also the symptoms not associated with the precordium which had been regarded as neurotic in origin disappeared. It was usually found unnecessary to inject the entire hyperalgesic area. Furthermore, ethyl chloride spray and, at times, saline solution intradermally and the oral administration of a red placebo were found equally effective. Cardiac neurosis, he concludes, is therefore a distinct entity with characteristics which can be recognized even in the presence of organic heart disease by the following criteria: an inherited or acquired predisposition to neurosis; a definite precipitating factor; symptoms such as inframammary pain and the others mentioned; inframammary tenderness and hyperalgesia; and, finally, relief by simple procedures such as intradermal injection of small quantities of procaine hydrochloride, together with suitable suggestion, the latter being the more important.

Other aspects of this problem have been recently emphasized by Professor Ryle² in the third Croonian lecture delivered at the Royal College of Physicians this year. Ryle states that there are no good grounds for regarding simple paroxysmal tachycardia as an expression of cardiac disease or intoxication. Its intermittence, its persistence through long years without physical deterioration, its temperamental and other associations, and the absence of all organic signs bring it within the category of the neuroses. Similarly, vasovagal attacks (Gowers' syndrome) belong, he feels, in this same group. Vasovagal attacks almost invariably occur in persons who are simultaneously afflicted by some slight impairment of general physical fitness and by a chronic or recurring anxiety—thus illustrating the combined influence of several factors which would seem to underlie so many of the neuroses. The menopause, a low-grade infection or anemia, a sudden visceral disturbance, colonic irrigation, or a severe bout of seasickness may serve as precipitating factors. On this basis, Ryle suggests that some violent vasomotor disturbance with accompanying vagal effects, manifest especially in the occasional bradycardia, seem to afford the best explanation of the attacks. Multiple visceral neuroses rarely occur together in point of time. Ryle points out. They alternate in a history or appear at different periods in a patient's life. In this respect there is an essential difference between so-called allergy and the more pronounced and specific anaphylactic response. Therapy should involve, he believes, first and essentially an assured diagnosis confidently stated. The second essential is a simple and reassuring explanation of the nature and genesis of the visceral symptoms themselves and of their innocence so far as life and ultimate prospects are concerned.

The study of the visceral neuroses is, Ryle concludes, a study of men and women, of personalities and temperaments, of heredity, habits and environments, and

of peculiar biologic responses to common but often inconspicuous stimuli. Possibly the explanation of the visceral neuroses and of their tendency to be perpetuated over long periods may invoke an inborn nervous instability, the conditioned reflex or habit, endocrine imbalance, and allergic sensitivity, operating severally or in conjunction. Although with the aid of physiologic and pharmacologic experimentation better measures of counteraction and symptom-relief may be found, it is Ryle's belief that in the end the understanding and best protective contributions are likely to derive largely from a clearer knowledge of the whole man and from improved diagnostic achievement.

HUMAN REPRODUCTIVE PATTERNS

Many factors influence human reproductivity, which in the last analysis determines world populations both qualitatively and quantitatively. The results of long years of study of the biologic and statistical factors involved, interspersed with personal lines of thought which have been provoked thereby, furnishes the subject of a recent book by Pearl.¹ Both the survival urge and the reproductive urge have a fundamental biologic role in influencing reproductive patterns, and there are recognizable differences in the strength of these factors. Just as there are demonstrable differences in the libido, there is likewise no reasonable doubt of variations between individual human beings in respect to innate reproductive capacity, though these are extremely difficult to measure precisely. One definitely determining factor is the limited span of reproductive life in the human female. Less important—because it varies less frequently and to a lesser degree—is the litter size or frequency of multiple births. Closely related to libido is the frequency of coitus, which, as Pearl points out, because of the restricted period available for successful fertilization, plays a large part in determining the fertility rate. This rate varies greatly with different individuals. Another element is what Pearl calls the pregnancy or conception rate in relation to the extent of time during which it is biologically possible for a woman to become pregnant. An additional factor is that reproductive wastage which is characterized by miscarriage or abortion, or by stillbirth. This wastage is most difficult to determine with any degree of accuracy, although there is ample evidence, Pearl believes, that reproductive wastage is a biologic factor of major importance in differentially influencing fertility as realized or expressed.

Finally—and because this factor has never been adequately ascertained and is most difficult to determine—the part played by contraceptive efforts in influencing fertility is subjected by Pearl to as close analysis as circumstances would allow. The evidence available has been marshaled in impressive fashion. Although future

additional information may lead to entirely different conclusions, Pearl's present views seem to be based squarely on the evidence presented. "One consistent broad result emerges," he says. "It is that if it were not for the effect of contraceptive efforts and the practice of criminal abortion, together with correlated habits as to postponement of marriage, there would apparently be little or no significant differential fertility as between economic, educational or religious classes of urban American married couples. In the absence of these forces the weight of the evidence as a whole is that all these socially differentiated classes would manifest about the same degree of fertility (with some possible reservations regarding the lowest educational classes). There would probably be some small residual differences, but they would not be great enough to worry any person of a realistic, practical cast of mind." This conclusion, better documented than most of similar nature, furnishes no surprise. The question whether, in essence, this differential represents a biologic phenomenon with biologic purposes or whether it can and should be altered by conscious human effort, Pearl wisely leaves unanswered.

The differential rates of fertility vary not only as between economic or social groups but also along geographic and genetic lines. It is noteworthy in this connection, however, that the greatest percentage decline in birth rates in the last third of a century has occurred predominantly in those countries having the highest previous birth rates. Likewise, the highest birth rates are now, with few exceptions, appearing in those geographic regions having the smallest population-area densities.

Whatever the relative importance of the factors influencing reproductive patterns in this country, the main facts are readily obtainable. Roughly, from 23 to 40 per cent of the women bearing products of conception in 1930 were primiparas, an obviously high proportion when viewed from the angles of race survival and population growth. Furthermore, a definite though not now precisely ascertainable proportion of these primiparas will never bear any more children. It is evident, as Pearl says, that unless a woman bears more than one child in her lifetime she is not adequately reproducing even herself, to say nothing of her family (self and consort) or her strain. If in a given year a woman produces her fourth living child, she may be regarded as having adequately reproduced, Pearl says. When the adequate reproducers, as so defined, were compared with all women who actually reproduced in the years 1920 and 1930 (on a live birth basis), little difference in the ratios of the two groups was observed. While at first surprising, in view of the lowered birth rates between these two periods, this can be explained, he believes, by the drop in the percentage of women potentially capable of being mothers who actually became
